The best practices method of collecting performance data is by direct recording of student behaviors. Direct measurement of behavior enables the school psychologist to objectively document behavior change. The most frequently used method of measuring behavior is direct observation and recording. There are several methods of direct observation data collection, including frequency recording, duration recording, and interval recording. Each of these procedures has advantages and disadvantages. The selection of a measurement procedure should be driven by (a) the dimensions of behavior (i.e., topography, frequency, duration), (b) the goals of the intervention, and (c) pragmatic considerations such as time, resources, and competency of observers.

It is also important to convert raw data to rate measures. The relative occurrence and disruptiveness of behavior may change as a function of the length of the school day. For example, a student may display 12 occurrences of aggressive behavior during a 6-hour school day (a rate of 2.0 occurrences of aggressive behavior per hour) or 12 occurrences of aggressive behavior during a 3-hour school day (a rate of 4.0 occurrences of aggressive behavior per hour). The occurrence of aggressive behavior is actually very different when rate is considered. If only the daily total was reported, then the occurrence of those behaviors would be identical (i.e., 12 per day). By contrast, reporting of rate more accurately reflects the level of occurrence and disruptiveness.

The following sections include descriptions and examples of data recording procedures that are commonly used within single case experimental design methodology. The examples in Figures 1, 2, 3, and 4, in addition to illustrating examples of data recording procedures, provide examples of clear, unambiguous descriptions of behaviors.

FREQUENCY RECORDING

Frequency recording involves observing, counting, and recording the number of times a behavior has occurred. This procedure typically is used to record occurrences of discrete, low rate behaviors (i.e., behaviors that have a definite beginning and end and that do not often occur). Frequency recording, while often a very accurate method of recording discrete behaviors, tends to provide an underestimation of sustained behaviors (e.g., time on-task), an inaccurate record of very high rate behaviors, and the potential unreliabil-

Figure 2. Example of frequency recording procedure

Target Behavior:	Self-injurious face slapping
Definition:	Katrina raises her right hand to her face, and from a distance of 6 inches or greater, strikes herself in the face with the open hand.
Procedure:	using a tallying system, record each time that the hand strikes the face (i.e., each occurrence).
Self-injurious face slapping:	𝍸 𝍸 ||
Program hours:	6
Frequency:	12
Rate:	2 occurrences per hour

Figure 3. Example of duration recording procedure

Target Behavior:	Tantrum behavior
Definition:	A response set including 2 or more of screaming, crying, throwing objects/materials, flopping to the floor, and kicking objects.
Procedure:	using a stopwatch, record the length of time from the onset to the end of the behavioral response set.
Tantrum behavior:	2'4", 8'10", 9'00", 12'00"
Program hours:	6
Frequency:	4
Rate:	.67 per hour
Cumulative duration:	32 minutes
Average duration:	5.33 minutes per hour

Percent duration (i.e., percent of time in which person displayed tantrum behavior):

$$\frac{\text{32 minutes}}{\text{360 program minutes}} = .08 \quad = 8\%$$

Figure 4. Example of b-s partial interval recording procedure

Target Behavior: On-task behavior

Definition: visual, motor, and/or verbal active participation in tasks and activities

Procedure: 6 s partial interval recording procedure
Record a "+" in each 6 s interval if on-task behavior occurred (even for only a brief instance).
Record an "0" in each 6 s interval if on-task behavior did not occur.

	6	12	18	24	30	36	42	48	54	60
1 min	+	0	+	0	0	+	+	0	0	+
2 min	1	+	0	0	+	+	0	+	0	+

Percent occurrence =

$$\frac{\text{number of "+" intervals}}{\text{total number of intervals}} \text{ X } 100$$

Example:

$$\frac{10}{20} \text{ X } 100 = 50\% \text{ occurrence of on-task behavior}$$

ity of observations when behavior onset and cessation are difficult to discriminate. Figure 2 illustrates the application of a frequency recording procedure.

DURATION RECORDING

This procedure involves observing, timing, and recording the total amount of time a behavior has occurred. It is most applicable in recording continuous behaviors (e.g., sustained behaviors such as on-task and stereotypy). Duration recording is typically done by stopwatch and can be expressed as a percentage of time. It is difficult to use in measuring high rate, short duration behaviors, and multiple behaviors. Figure 3 illustrates the use of a duration recording procedure.

INTERVAL RECORDING

This procedure involves observing and recording the occurrence and nonoccurrence of behaviors at predetermined units of time (i.e., "intervals" ranging from several seconds to several minutes or even hours). Three types of interval recording procedures are (a) whole interval in which a behavior is recorded only if it was observed to occur during the *entire* interval, (b) partial interval in which a behavior is recorded if it was observed for *any part* of the interval, and (c) momentary time sampling in which the observer looks at the student only at predetermined intervals and notes if the target behavior is occurring at the precise moment the observation occurs.

Momentary time sampling procedures can be used to record a wide range of behaviors and allow for simultaneous observation and recording of multiple behaviors. While applicable to a wide range of behaviors, these procedures provide only an estimate of behavior. The reader is cautioned, however, that whereas whole interval recordings tend to underestimate the occurrence of behavior, partial interval recordings tend to overestimate the occurrence of behavior. Figure 4 displays a 6-s partial interval recording procedure that was used to measure the behavior of a student who had been referred to the school psychologist for functional behavior assessment of on-task behavior.

Of these three methods, whole interval recording is recommended when continuous occurrence of the target behavior is expected (e.g., when recording sustained attention to task). Partial interval recording is preferred for measurement of high-frequency, and rapidly occurring (e.g., self-injurious head banging) behaviors. Momentary time sampling is useful when continuous observation of a student is not practical, or when an observer is monitoring and measuring target behaviors with several students in one setting. It should be noted that interval recording procedures provide only estimates of rate and duration of occurrence of target behaviors. The results of observations are reported in terms of the number of percentage of intervals in which target behaviors occur. Of the interval recording procedures, partial interval recording is the most frequently used.

LIKERT-BASED INTERVAL RECORDINGS

These procedures involve observing and rating a behavior according to a predetermined scale as an estimate of occurrence, duration, and/or intensity of behaviors. Likert ratings can be used to record a wide range of behaviors. This procedure is typically used when frequency, duration, partial interval, or whole interval procedures are not practical given the professional responsibilities, resources, and experience of the observers. Likert-based interval recording procedures can be used simultaneously to record multiple behaviors (both adaptive and interfering). A particular advantage of this procedure is the capacity simultaneously to provide direct instructional/behavioral supports and recording of data. While Likert ratings of complex student behaviors have been found to have acceptable levels of reliability and validity (Steege & Davin, 1999), these methods may yield inaccurate results, especially with novice evaluators. Examples of the use of Likert ratings have included measures of the intensity of behavior (e.g., Iwata, Pace, Kissel, Nan, & Farber, 1990) and estimates of the relative occurrence of behavior (e.g., Romanczyk, 1996; Steege & Davin, 2000).

PERMANENT PRODUCT RECORDING

Another aspect of a behavior that may be recorded is its product. Permanent product recording is used when a behavior results in specific *tangible* outcomes (Miltenberger, 1997). This procedure involves recording the number of products (e.g., number of homework assignments completed, number of bottles sorted accurately). It is used to record a wide range of products, or outcomes, of behavior. One advantage of this method is that the observer need not be present when the behavior occurs. One possible drawback to this procedure is that practitioners cannot always determine who exhibited the behaviors that led to the product recorded. For example, a teacher cannot determine whether a student completed his or her own homework, whether assistance was provided, or whether someone else completed the assignments.

INTER-OBSERVER AGREEMENT

An important consideration in measuring student behavior is the reliability of the recording method. Reliability of measurement is usually defined in terms of inter-observer agreement. Inter-observer agreement refers to common findings by two or more observers or raters on the occurrence and nonoccurrence of target behaviors, the ratings of behaviors, or the ratings of permanent products. There are several methods of determining the degree of inter-observer agreement. The most commonly used method involves calculating the ratio of agreements to the total number of recordings of behavior. For example, suppose that using an event recording procedure to measure a student's social interactions during morning recess, two observers simultaneously and independently observed and recorded initiations of peer-directed social interactions. The primary observer recorded 12 occurrences of the target behavior while the secondary observer recorded 10 occurrences of the behavior. The total number of recordings of behavior was 12. The number of agreements was 10, resulting in the following ratio:

$$\frac{10}{12 = .83 =}$$

83% inter-observer agreement

Generally, an inter-observer agreement percentage at or above 80% or greater is considered the standard for concluding that the measurement of student behavior is reliable and valid. It is recommended that inter-observer agreement data must be conducted for 25–30% of the sessions/samples. During the evaluation of the effectiveness of an intervention, the school psychologist could serve as the primary observer/rater to measure student behavior, and a trained secondary observer/rater could be enlisted simultaneously, but independently, to measure student behavior. In situations in which a second observer/rater is unavailable, videotaping a sampling of sessions may be conducted. The videotape can then be viewed and behaviors recorded with a second observer.

Selecting a Design

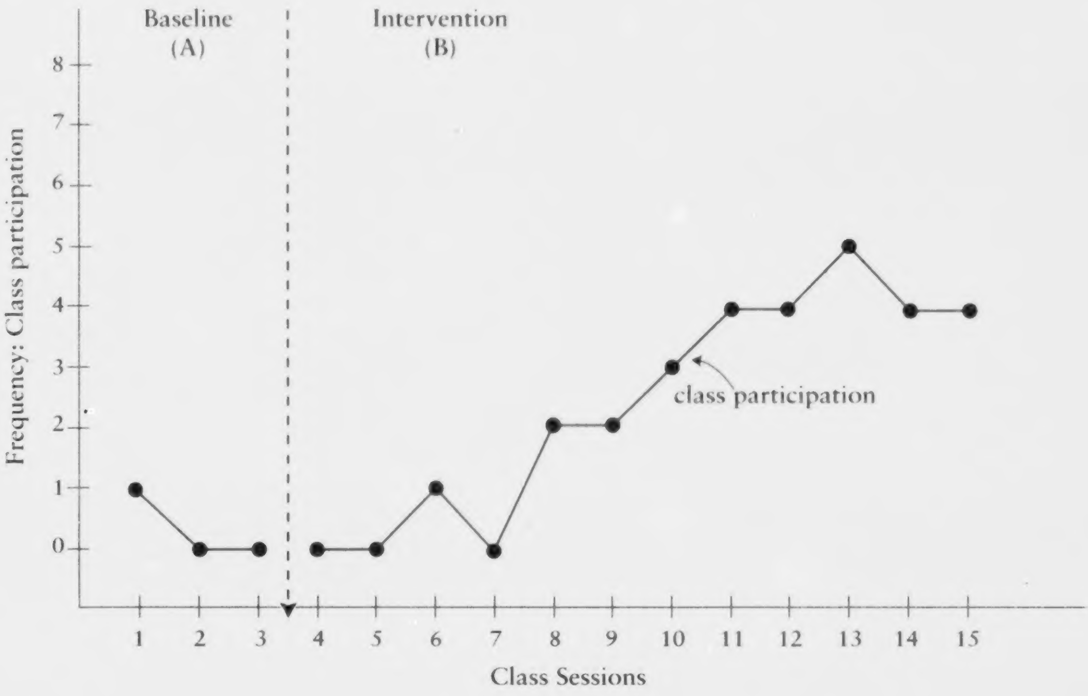
CASE STUDY (AB) DESIGN

The Case Study design is the most basic of single-case experimental designs (Polaha & Allen, 1999). This design simply includes a baseline phase (A) and an intervention phase (B). First, baseline measures are repeatedly taken until stability in behavior is demonstrated. The intervention then is introduced and an appropriate number of measurements are made during this second phase. If, according to the data, behavior improves during the intervention phase, then the effectiveness of the intervention is presumed to have been demonstrated. Figure 5 illustrates an example of the Case Study (AB) method.

In this example, class participation was defined as raising a hand and, when called upon verbally, contributing relevant information to the class discussion. The team reviewed various data recording procedures and decided that a frequency recording procedure would yield the most accurate and valid measures of class participation. During Baseline (A), the teacher lead class discussions and recorded the number of times that the student exhibited the target behavior; this ranged from zero to one time over three sessions. The intervention involved several components, including (a) an advanced organizer that outlined key issues of the discussion, (b) a rehearsal strategy, and (c) self-monitoring. When the intervention package was implemented, an increase in class participation behavior was observed. Over time, class participation increased to a stable level of responding. Social validity measures, involving the recording of class participation of classmates, indicated the intervention resulted in levels of class participation that was comparable to 80% of the student's peers.

While the results of this investigation suggest that increased class participation was directly related to

Figure 5. Example of case study (AB) method



the intervention, it is not fully known whether the behavior change resulted from the treatment or from extraneous variables, or whether class participation would have increased naturally without the intervention. It is most often used in applied, non-research situations where practitioners are primarily interested in documenting and facilitating behavior change (Miltenberger, 1997). Thus, while the AB method may be useful for documenting a student's progress, it does not allow us to demonstrate a functional relationship between the intervention and the changes in student behavior. To control for rival hypotheses, and to demonstrate a functional relationship between the intervention and behavioral outcomes, the school psychologist must use a more sophisticated experimental design.

ABA AND ABAB DESIGNS

These designs are initially identical to the case study method; however, following the intervention phase a return to the baseline conditions is introduced (i.e., the intervention is briefly withdrawn, depicted as ABA). If the student's behavior is improved during the intervention phase and then reverses to baseline levels when the intervention is withdrawn, then a functional relationship and, thus, the effectiveness of the intervention, has been demonstrated. In short, with an ABA design, improvements in behavior occur only when the intervention is being implemented.

A major concern with an ABA design is an ethical one, because the intervention is terminated with the student not receiving what has been demonstrated to be effective. To address this issue, a return to the intervention phase is recommended. The ABAB design is identical to the ABA design with the addition of a replication of the intervention. In addition to addressing ethical objections to an ABA design, the ABAB design strengthens the conclusion about the effectiveness of the intervention by demonstrating positive treatment effects twice. In short, the second B phase is a systematic replication of the intervention.

A number of considerations must be taken into account when using the ABAB design. First, the withdrawal of an effective intervention may result in the recurrence of dangerous behavior (e.g., self-injury, aggression). Second, one must be fairly certain that the behavior will return to baseline levels when the intervention is withdrawn. If the behavior fails to change when the intervention is withdrawn, then a functional relationship is not demonstrated (Miltenberger, 1997). Finally, one needs to consider if indeed it is possible to withdraw the intervention. If the intervention involved teaching a skill, then one sometimes cannot simply withdraw the learning that has occurred.

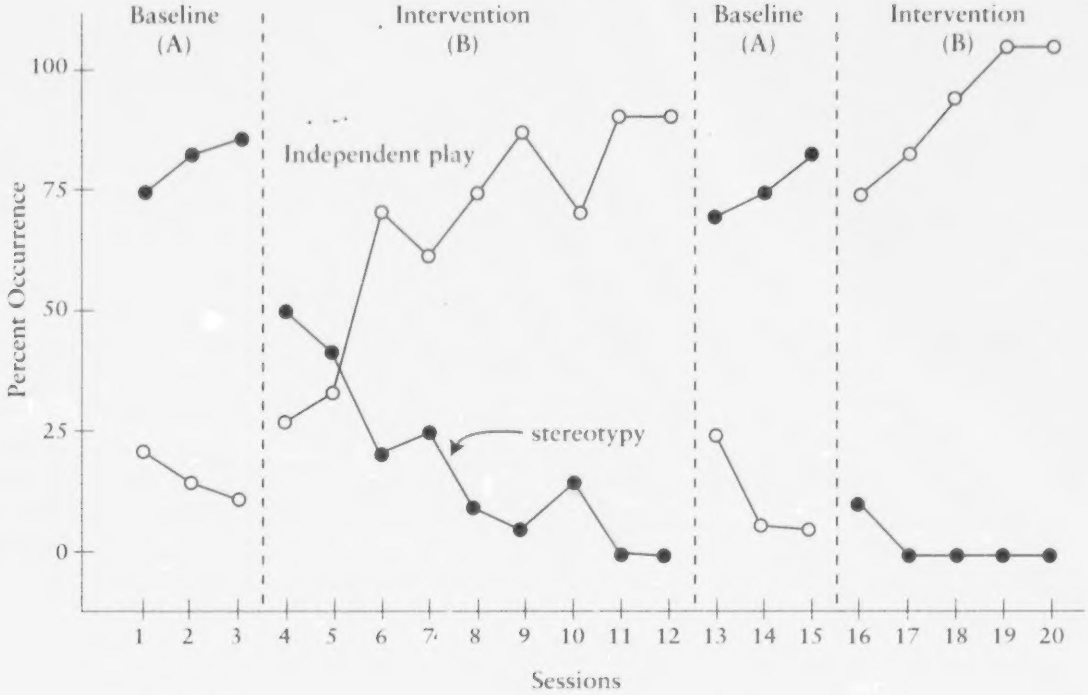
Figure 6 illustrates the application of an ABAB design. In this example, the school psychologist collaborated with the special education teacher in developing and implementing an intervention that *increased* the independent play behavior and *decreased* stereotypic behavior of a student with autism. Independent play and stereotypes were operationally defined and measured by using a 10-s partial-interval recording procedure. During the initial baseline phase (sessions 1, 2, and 3), high levels of stereotypic behavior and low levels of independent play were recorded. During the initial intervention phase, the student was instructed to use a picture activity schedule that served to guide him through a series of preferred play activities. The intervention resulted in marked increases in independent play behavior and decreases in stereotypic behavior.

To demonstrate that the picture activity schedule was a necessary component of the intervention, it was withdrawn (second A phase) for three play sessions, resulting in a return of target behaviors to baseline levels of responding. When the picture activity schedule was reintroduced (second A phase), stereotypic behavior decreased and independent play behavior increased. This design demonstrated a functional relationship between picture activity schedules and an increase in independent play as well as a decrease in stereotypy.

MULTIPLE BASELINE DESIGNS

Multiple baseline designs are an extension of the case study methodology. With multiple baseline designs, functional relationships between the intervention and target behaviors can be inferred according to the following criteria: (a) repeated measurement of a behavior across a minimum of two baselines, (b) lagged introduction of treatment across baselines, (c) immediately observed effects of intervention, and (d) no observable effects in conditions in which the intervention has not been implemented (Rusch, Rose, & Greenwood, 1988). Multiple baseline designs are frequently used to evaluate the effectiveness of interventions, particularly for those interventions in

Figure 6. Example of withdrawal (ABAB) design



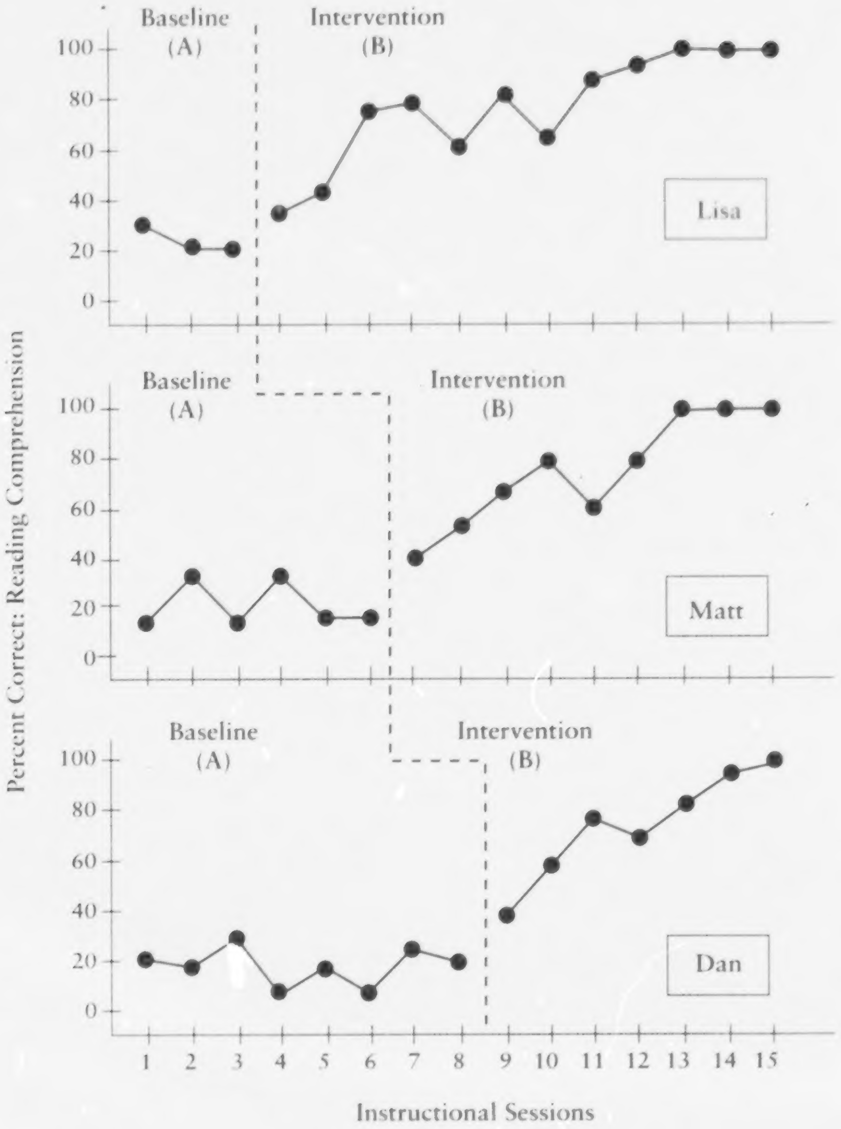
which it is not practical to utilize a withdrawal condition (i.e., when target behavior is not expected to return to baseline if the intervention is taken away).

Generally, there are three types of multiple-baseline designs. In a multiple-baseline-across-subjects design, there is a baseline and a treatment phase for the same target behavior of two or more different subjects. In a multiple-baseline-across-behaviors design, there is a baseline and treatment phase in the same setting for two or more different behaviors of the same subject and setting. Finally, with a multiple-baseline-across-settings design, there is a baseline and treatment phase for two or more settings in which the same behavior of the same subject is measured.

For example, the school psychologist might use a multiple-baseline-across-behaviors design to evaluate the effectiveness of an intervention sequentially to teach a student with developmental disabilities three different community living skills (e.g., laundry skills, public transportation skills, personal grocery shopping skills). By utilizing a multiple-baseline-across-students design, the school psychologist could evaluate the effectiveness of a social skills training intervention to increase the prosocial behavior of five students in the context of a mainstream class. Similarly, the school psychologist could use a multiple-baseline-across-settings design to evaluate the effectiveness of a social skills training intervention to increase prosocial behavior of one student in five different educational settings.

Figure 7 illustrates the multiple-baseline-across-subjects design. This graph shows the effects of an intervention designed to increase reading comprehension skills of three students with learning disabilities. Reading comprehension was measured through the use of permanent product recording where students first read passages from assigned materials and completed a 10-item worksheet covering the content of the story. With this design, baseline data were collected for all three students. After the behavior of each student had reached a stable level, the intervention procedure was implemented for only one of the students (Lisa) while baseline conditions continued for the other two (Matt and Dan). Once Lisa demonstrated improvement in behavior, the intervention was applied to Matt, while baseline continued for Dan. Finally, when both

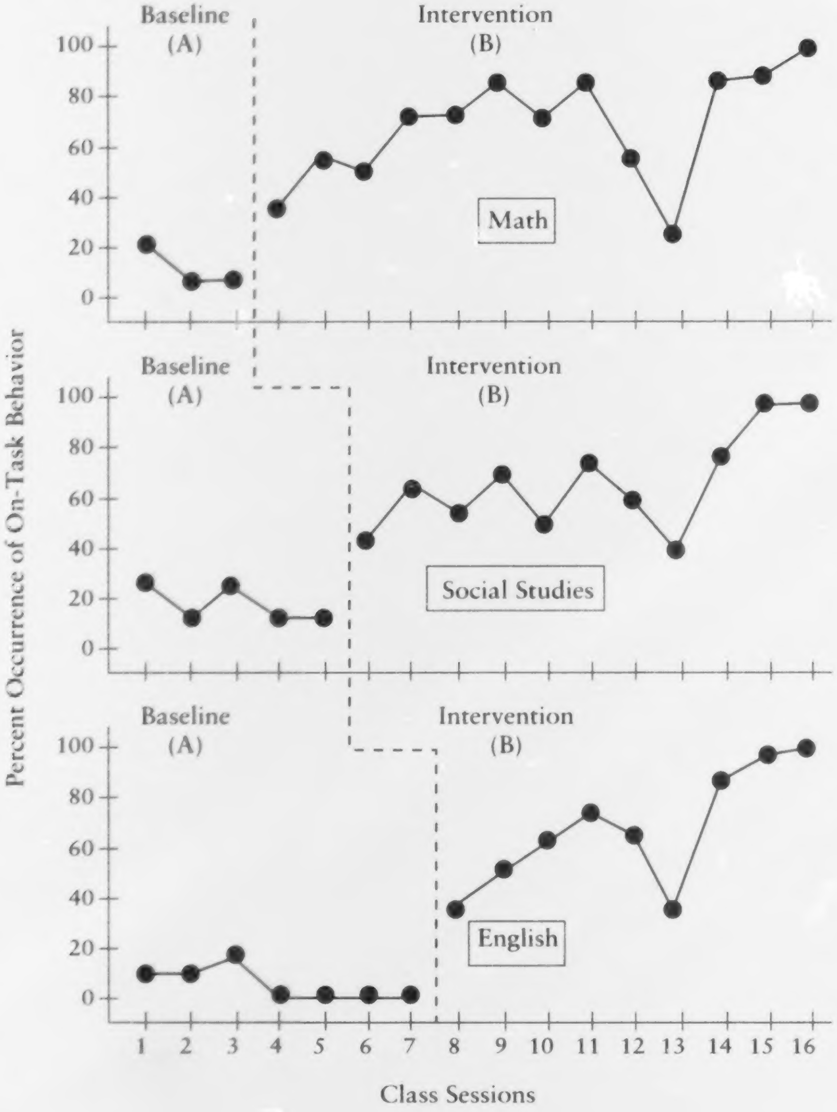
Figure 7. Example of multiple-baseline-across-students design



Lisa and Matt demonstrated behavior change, the intervention was implemented with Dan, resulting in increased reading comprehension skills. This study demonstrated a functional relationship between the intervention and behavioral outcomes by systematically replicating intervention effects across multiple students following stable baselines.

Figure 8 shows an example of a multiple-baseline-across-settings design. In contrast to the previous example that included three students where Matt and Dan served as "controls" for Lisa, and Dan serving as a control for Matt, in this design Arlene serves as her own control. Specifically, in this example the school psychologist collaborated with the team in developing and implementing an intervention designed to increase on-task behavior during three independent seatwork sessions with one student (Arlene). By using a 10-second whole-interval recording procedure, the

Figure 8. Example of multiple-baseline-across-settings design

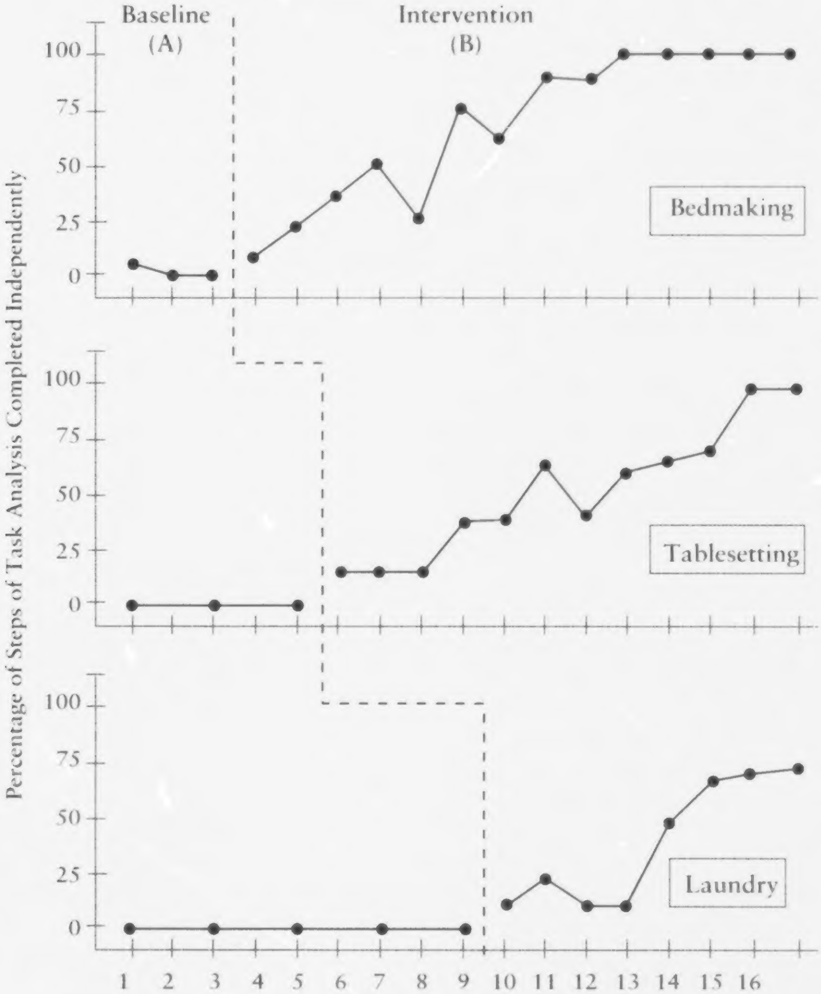


school psychologist observed Arlene during assigned independent seat work activities for three consecutive days. Beginning on the fourth day, the classroom teacher provided in vivo coaching with Arlene in the use of a self-monitoring procedure. Baseline measures of on-task behavior continued in the other two settings. On the fifth day of the project, the classroom teacher again implemented the in vivo coaching of self-monitoring, and Arlene exhibited increased gains in on-task behavior. In contrast, and as a control, Arlene continued to maintain steady rates of lower on-task behavior during the other two settings. On the sixth day, the classroom teacher provided the third session of coaching in self-monitoring with Arlene during math and the first session of coaching in social studies. This resulted in an increase of on-task behavior in both settings. Within the third setting, where Arlene had not been exposed to the intervention, she continued to display steady but low rates of on-task behavior. Beginning with the eighth day, Arlene was coached in the use of the self-control procedures in all classroom settings. This intervention demonstrated that in vivo coaching in self-monitoring techniques resulted in increases in on-task behavior for Arlene across settings.

A variation of the multiple baseline design is the multiple probe design. The multiple probe design involves the same components of multiple baseline designs except that fewer measures of the target behavior are required (Steege & Wacker, 1995). Multiple probe designs are typically used when repeated measures during baseline may be harmful to the student, and/or extended baselines may potentially result in either an increase or decrease in the target behavior(s).

A multiple-probe-across-behavior design is illustrated in Figure 9. This graph shows the effects of an intervention utilizing systematic instruction procedures (i.e., task analysis, prescriptive prompting, and contingent reinforcement) to teach three functional life skills to a student with developmental disabilities. Because of the possible negative impact of extended baseline sessions, the team opted to use a multiple probe design across behaviors. The dependent variable was the percentage of steps of the task analysis the student completes independently for each task. As

Figure 9. Example of multiple-probe-across-tasks design



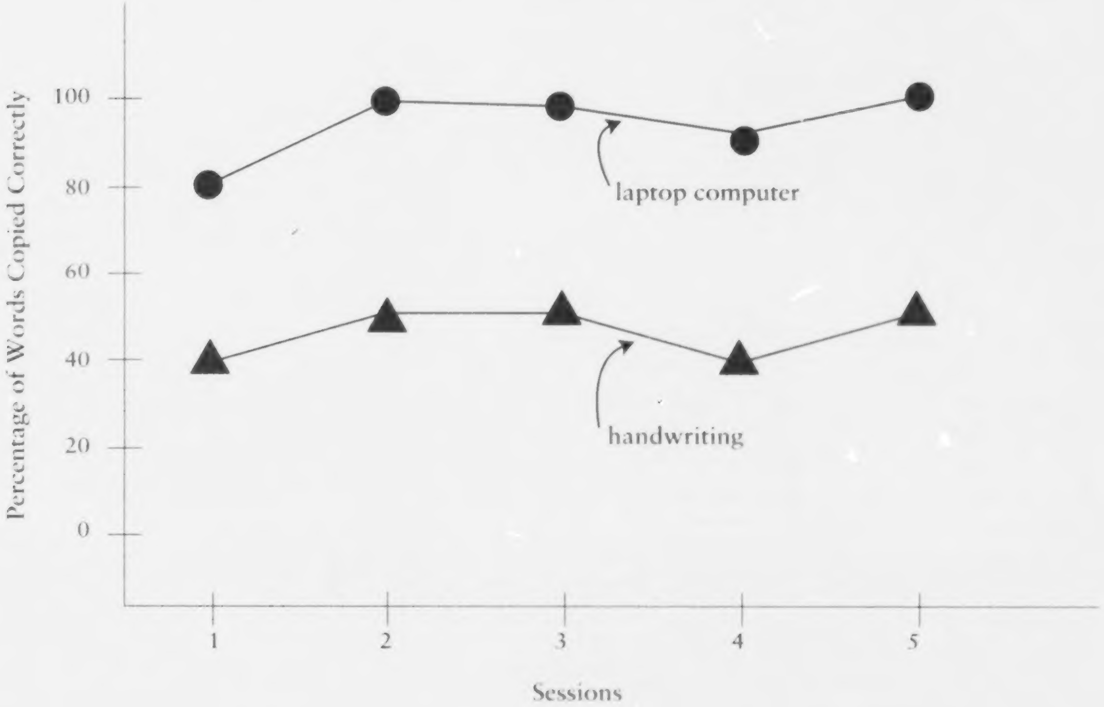
shown in Figure 9, during baseline, Don was asked to complete each of the three tasks and was provided no additional assistance. Baseline data demonstrated that he was able to complete a small percentage of the steps involved in each task. When, and only when, systematic instruction was provided, he displayed a marked improvement in performance. The intervention is staggered across the three behaviors and each behavior changed only after the intervention is applied to that behavior. Because each of the three behaviors changed only after the implementation of the intervention, a functional relationship was demonstrated.

ALTERNATING TREATMENTS DESIGN

Alternating treatments designs are used to assess the relative effectiveness of two or more treatments (i.e., interventions) for a single subject. The alternating treatments design has been referred to by a variety of different terms: multiple schedule design, multi-element design, multi-element manipulation design, and simultaneous treatment design. With an alternating treatments design, two or more treatments are presented to the student in a random or counterbalanced order. Because conditions are presented alternately, there should be no carryover effects with respect to behavior from one treatment trial to the next. This design is especially useful when the educational team is interested in determining which of two or more interventions is more or less effective (Kazdin, 1994). With this design, a comparison can be made between a baseline condition and an intervention between two or more interventions.

Consider the following example of an alternating treatments design. Mary Ann, a student with cerebral palsy and a learning disability in the areas of reading and written language (see Figure 10), experienced extreme difficulties in completing written assignments (e.g., defining vocabulary words, worksheets). During previous school years, Mary Ann had been expected to complete all written assignments using a pen and pencil. While successful during the Kindergarten through third grades, she was experiencing great difficulty in completing written

Figure 10. Example of alternating treatments design



assignments during fourth grade. The school psychologist and special education teacher recommended that Mary Ann be provided with and taught to use a laptop computer to complete written assignments. They hypothesized that by providing her with a laptop computer she would demonstrate an increase in the efficiency, quantity, and quality of written work. Previous recommendations for providing students with laptop computers had been met with resistance by school administration. The special education teacher and school psychologist decided to collect data on the efficacy of their recommendation. They speculated that by demonstrating a functional relationship between the laptop computer and improvements in written language performance, that the team would be very likely to agree with the recommendation for the purchase of a computer for Mary Ann. To test their hypothesis, the school psychologist and special educator used an alternating treatments design to compare the relative effectiveness of the laptop vs. pen/pencil in writing performance.

The school psychologist began the intervention by determining a random assignment in the order of presentation of the two treatments (i.e., laptop versus pen/pencil). Next, the intervention team identified a specific context (e.g., classroom activity) that would be held constant across the presentation of the treatments. They selected a task requiring Mary Ann to copy (or type) the definitions of 10 vocabulary words. Each definition required approximately the same number of words and letters. Ten word lists were identified. Mary Ann was directed to use a pencil to write the definitions for five of the word list and to use a laptop computer to type the definitions for five of the word list. The dependent variable was number of words copied accurately within 10 minutes. The intervention was conducted over 3 days to reduce the potential confounding variable of fatigue. One session was conducted each day, with each session including one trial using the laptop and one trial using pen/pencil. The results of the intervention clearly demonstrated that when compared with handwriting, the word-processor strategy consistently resulted in higher levels of performance. Thus, for this student, the intervention team could prescribe with confidence the laptop computer intervention as a method of increasing written language performance.

CHANGING CRITERION DESIGN

The most basic changing criterion design is an AB design in which performance criteria are set for specified consequences to occur if the target behavior reaches or exceeds the criterion level. The performance criteria shift in a stepwise fashion after stability occurs at each criterion level. For example, a changing-criterion design was used to evaluate the effectiveness of an intervention designed to increase walking/jogging behavior with students with disabilities in an adaptive physical education program. Walking consisted of walking around a 200-meter indoor track at the school athletic complex for 30 minutes each school day. The distance covered within the 30-minute period served as the dependent variable.

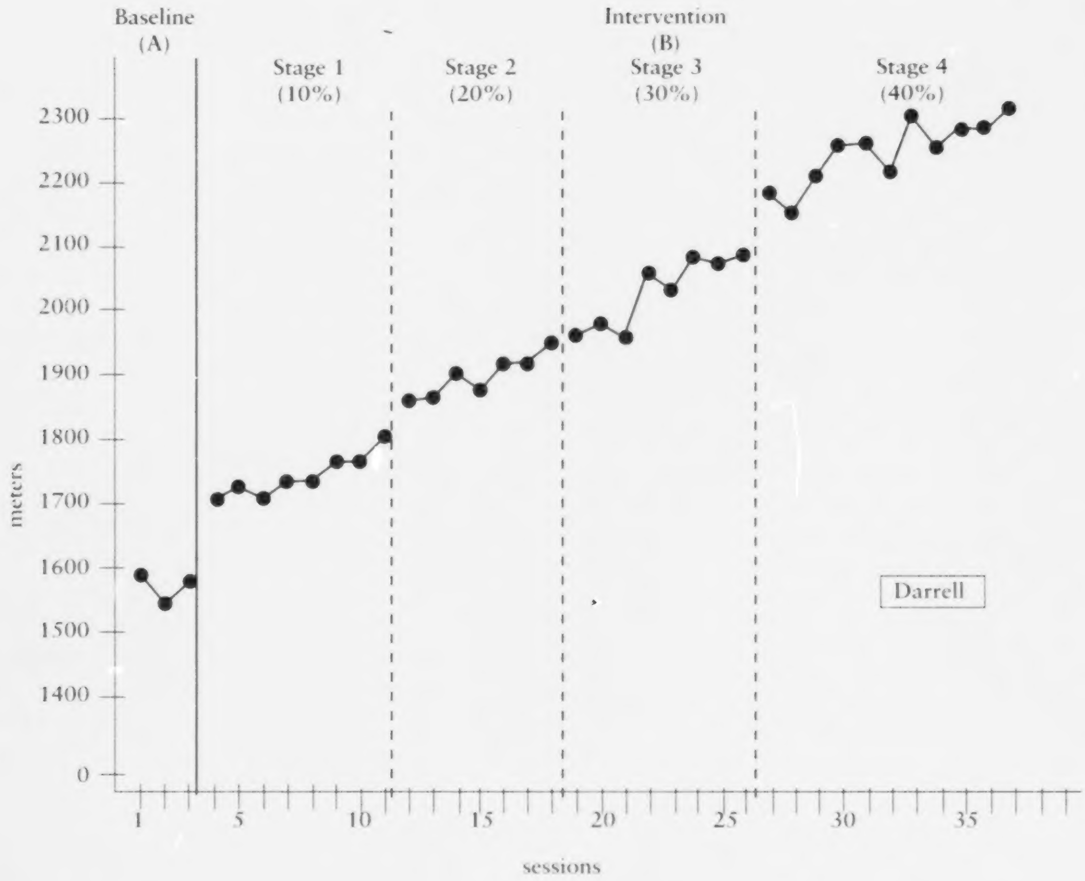
During baseline, each student was told to walk around the track as many times as they liked for a 30-minute period. Following baseline, an intervention package incorporating token reinforcement and self-monitoring components was introduced. Tokens could later be exchanged for gym shorts, running T-shirts, and clothing that depicted school athletic team. Self-monitoring consisted of each student maintaining a walking/jogging log. Criteria for earning reinforcement changed sequentially throughout the intervention. During stage 1, students earned reinforcement when they increased distance walked by 10% over average baseline level of performance for three consecutive sessions (e.g., a student who walked 1,600 meters during baseline needed to walk 1,760 meters to earn reinforcement). Stage 2 required a distance of 20% greater than baseline (1,920 meters), stage 3 required 30% greater than baseline (2,080 meters), and stage 4 required a distance that was 40% farther than the baseline level of performance (2,240 meters).

Figure 11 illustrates the changing-criterion design with one student. During baseline, Darrell walked 1,600 meters or less in 30 minutes. By the eighth session, he was walking 1,800 meters in 30 minutes and had earned the token reinforcement. Beginning with the ninth session, the criterion was increased to 1,920 meters during the 30 minutes. Darrell quickly met the criterion and sequentially continued to meet each criterion shortly after it was introduced.

Collecting Baseline Data

Baseline, also referred to as the "A" phase, is the initial phase of the study when target behaviors are mea-

Figure 11. Example of changing criterion design



sured prior to the implementation of the intervention. Baseline data describe the individual's current level of performance prior to intervention and can be used to predict the levels of future behaviors if no intervention is applied. The baseline measurement of the target behaviors will then be used as the basis for comparison to evaluate the effects of the intervention, comparable to the way in which a non-treatment control condition is used in group designs or how a pretest is used (Fugate & Furlong, 2000).

During the baseline phase, the student's behavior is measured for several sessions until a stable pattern of behavior has been established. Baseline must continue until stability in the behavior is demonstrated. Generally, a stable trend in behavior is determined when the rate of behavior is steady or if it continues in a direction that is the opposite of the expected intervention outcome (e.g., a decreasing trend in rate of adaptive behavior when the intervention is designed to increase adaptive functioning). While minimum of three data points indicating a definitive trend in responding is recommended, the following case examples each illustrate stable trends of behavior during the baseline and intervention phases. Baseline rates can at times be quite variable. In such cases it is important to continue collecting baseline data until a pattern of variability is established, however, there are ethical and practical limitations to extended baselines. For example, withholding an intervention designed to address severe aberrant behaviors until a stable baseline occurs may be problematic. In general, the school psychologist needs to collect at least enough baseline data to demonstrate pre-intervention levels of responding.

Implementing Intervention and Ongoing Collection of Data

Given that the focus of this chapter is evaluating the effectiveness of interventions, procedures for designing and implementing specific interventions are not discussed. It is important that the behaviors targeted for change be measured directly before and during the implementation of the intervention. It is the data concerning a student's specific target behaviors that reveal whether an intervention is effective. Recording target behaviors during the intervention phase allows for continuous evaluation of the effectiveness of the intervention.

Frequent questions asked by practitioners are, How often should we collect data? or How much data do we need to determine the effectiveness of the intervention? There is no simple answer to those questions. Basically, a sufficient amount of data needs to be collected over time to demonstrate a functional relationship between the intervention and target behavior. The number of data points needed to determine the efficacy of an intervention will vary across individuals, target behaviors, interventions, and settings. Thus, it is important to collect enough data during the baseline phase to establish pre-intervention trends. A rough guideline for number of data points for baseline is three similar (i.e., stable) examples of the identified behavior of concern. There must be a sufficient number of samples of the behavior so that a baseline level can be computed and used to compare the rate or level of any subsequent changes once the intervention is implemented. Similarly, the number of intervention data points must be sufficient for a valid comparison of baseline and intervention phase behaviors. This number will depend on the type of behavior; however, a minimum of five data points is recommended.

Once a stable baseline is achieved, the planned intervention is implemented. It is important that the intervention be implemented accurately. The usefulness of the data is enhanced if the intervention is conducted exactly as planned. The team should refrain from modifying the intervention unless the changes are incorporated within the evaluation design. Readers interested in issues of intervention adherence and integrity are referred to Telzrow (1995).

Analyzing Results

Data collected throughout baseline and intervention phases should be displayed in graphic form as shown in the previous examples. Improvement in behavior is determined by examining the differences between baseline trends in responding with intervention trends. Basically, if the target behavior changed in the desired direction during intervention, and potential confounding variables were minimized, then a functional relationship between the intervention and the target behavior has been demonstrated. Even if there is improvement in a target behavior from baseline to intervention, it cannot be concluded necessarily that the change was sufficient (Bloom, Fischer, & Orme, 1995). Interventions are considered to be clinically significant when intervention objectives are attained or surpassed. Readers interested in additional information regarding the analysis of singe case experimental design are referred to sources listed in the annotated bibliography (i.e., Bloom et al. (1995) include several chapters focusing on analysis of data).

SUMMARY

This chapter introduced some of the underlying assumptions and strategies for accurately measuring students' behavior and for systematically evaluating the effectiveness of interventions. Systematic evaluations of interventions document meaningful behavior change and result in improved programming for students. School psychologists increase the accountability for their services by collecting data about student behavior and by demonstrating functional relationships between an intervention and its outcome. This is becoming increasingly important for several reasons. First, the role of school psychologists continues to expand beyond traditional diagnostic assessment to models of consultation, direct interventions, and applied research. Single-case experimental design is the method of choice in evaluating student performance and for documenting the effectiveness of services. Second, federal and state regulations pertaining to special education services require individualized educational programs that include measurable objectives of student performance. Moreover, these regulations require the ongoing measurement of student performance. In other words, teams are required to directly measure a student's progress relative to each behavioral objective. School psychologists are often uniquely trained and qualified to develop reliable and accurate data recording procedures and to assist the team in the design and implementation of methodologies for evaluating intervention effectiveness. Finally, consumers of psychological services are increasingly interested in objective measures of student performance. Students, their families, and the professionals serving them deserve objective analyses that demonstrate that the interventions implemented by the team are responsible for improvements in student behavior. Moreover, such practices enable the team to efficiently identify ineffective interventions. This helps practitioners make modifications in interventions, thereby increasing the efficiency and effectiveness of educational programming. The best practices method of demonstrating the effectiveness of interventions includes direct measures of behavior and single-case experimental designs.

ANNOTATED BIBLIOGRAPHY

Bloom, M., Fischer, J., & Orme, J. G. (1995). *Evaluating practice: Guidelines for the accountable professional.* Boston: Allyn & Bacon.

This book is a comprehensive review and explanation of procedures for evaluating interventions. Chapters cover in detail topics such as measuring behaviors, specific evaluation designs, and procedures for analyzing results. Numerous examples are included.

Fugate, M. H., & Furlong, N. E. (2000). Single subject research design. In N. E. Furlong, E. A. Lovelace, & K. Lovelace (Eds.), *Research methods and statistics: An integrated approach.* Fort Worth, TX: Harcourt-Brace.
In this chapter the authors discuss several single case experimental designs and the major issues involved in the interpretation of their results. Clinical examples are infused throughout the chapter as the authors review the key elements in designing, implementing, and critiquing single case research.

Lundervold, D. A., & Belwood, M. F. (2000). The best kept secrets in counseling: Single-case ($N = 1$) experimental designs. *Journal of Counseling & Development, 78,* 92–102.
This article proves a context and rationale for using single-case experimental design procedures as in the evaluation of the effective of counseling services. The authors discuss a seven-component model for establishing the use of single-case experimental design methodology within counseling programs.

Kazdin, A. (1994). *Behavior modification in applied settings.* Pacific Grove, CA: Brooks/Cole.
This book offers two chapters that discuss procedures for (a) identifying, describing, and assessing behavior and (b) implementing and interpreting single case experimented designs. Additionally, numerous examples of single-case experimental designs are discussed throughout the remaining chapters.

Polaha, J. A., & Allen, K. D. (1999). A tutorial for understanding and evaluating single subject methodology. *Proven Practice, 1,*73–77.
This article first describes the essential characteristics of single case experimental designs and then provides examples of four common designs and their application within classroom settings. The article also includes a set of key questions to ask when practitioners critically evaluate single case experimental designs.

36 Best Practices in Reintegration and Special Education Exit Decisions

Lockland City Schools

OVERVIEW

The way we define or frame a problem, to a large degree, supports or hinders our search for solutions. For example, if an individual's needs are framed around finding the levels of support needed to progress toward specified goals, our search should result in the generation of intervention ideas. Within a problem-solving paradigm, the focus of the special education (SE) identification process is defining the accommodations and modifications that will help a child succeed in the educational environment. Identifying and measuring a student-centered deficit or the magnitude of a discrepancy in achievement or behavior becomes somewhat less important. Rather, measuring an intervention's effectiveness through progress monitoring and data collection becomes the focus of our efforts.

Special education was intended to be a "problem-solving system" for general education (Deno, 1989). School psychologists now have the measurement technology that links assessment of individual needs to interventions. A current research base exists for choosing effective instructional practices and interventions. Methods to monitor students' academic and behavioral progress relative to general education (GE) expectations also are available. Thus, it is incumbent upon school psychologists to use the available knowledge base to assist educators in implementing effective instructional programs that include plans for returning SE students to GE environments. The purpose of this chapter is to outline a set of best practices to assist school psychologists and other educational professionals in meeting this goal.

Reintegration Defined

Reintegration involves determining when it is appropriate to fade and eventually remove SE services for a student. For the purposes of this chapter, reintegration will be described as the process that occurs on a trial basis prior to a more permanent removal of SE services. This process is tied to a specific set of data-based, decision-making steps. Reintegration is not an all or nothing judgment about a student's need for SE, but is best viewed along a continuum. Thus, reintegration may be considered for a single domain (e.g., reading) or for several domains of functioning (e.g., reading, science, physical education). The process also is not restricted to students receiving SE services for academic difficulties. Reintegration may be appropriate for students receiving services for behavioral and emotional difficulties, communication and language problems, physical disabilities, and so on. Thus, the process is appropriate to consider for any student receiving SE services.

Terms most often associated with reintegration, but that may carry different meanings, include "mainstreaming" and "inclusion." Mainstreaming often refers to placing students who receive SE services into environments with non-disabled peers for the purposes of receiving instruction in a less restrictive setting or for social/emotional benefits to the SE student. Students who are referred to as "mainstreamed" typically are not involved in a systematic process geared toward eventual exit from SE. Rather, their mainstream placement is part of their Individual Education Plan (IEP) with goal monitoring by the SE teacher(s). Research on mainstreaming has focused more on the effects for SE students already in GE. In contrast to mainstreaming research, reintegration studies usually have focused on the process by which students return to GE for instruction (Fuchs, Roberts, Fuchs, & Bowers, 1996).

Reintegration also carries a different meaning than the term "inclusion." Often used with the descriptor "full," inclusion refers to instructing all students receiving SE services, regardless of disability category, with non-disabled peers. Inclusion generally is not a process geared toward eventual exit of the SE student, but rather attempts to reduce the segregation of students with disabilities regardless of the degree or severity of disability. Thus, inclusion decisions tend to be large-scale, values-based decisions.

Background Information and History

Considering reintegration is important for a variety of reasons including economic concerns, socio-political issues, and legal parameters. A primary economic concern is the continued exponential growth of SE and the expenses associated with this growth. According to the twenty-second Annual Report to Congress on the implementation of the Individuals with Disabilities Education Act (IDEA) (U.S. Department of Education, 2000), 5.5 million students were served in SE or 12% of all children enrolled in public schools in 1998–1999. Of the children served in SE, more than 78% (or 4.7 million) were identified as those with mild disabilities (e.g., specific learning disabled (50%), speech and language impaired (20%), and emotionally disturbed (8%)). The overall number of children in SE represents an increase of 2.7% over the previous year and a 30.3% increase over the past decade. The costs associated with this growth are enormous. In fiscal year 2000, more than $4.9 billion was appropriated for Part B of IDEA, Section 611. Estimates of current total dollars spent on these services range from $30.9 to $34.8 billion per year with the average per pupil spending estimated at $5,435 (Parrish, 1999). To complicate matters, many students identified with mild disabilities never exit SE despite being the most likely candidates for reintegration. Available data suggest that as few as 2–6% exit each year (Lytle & Penn, 1986; Shinn, 1986).

Reintegration is tied historically to the Regular Education Initiative (REI). The REI achieved prominence in the late 1980s after Assistant Secretary of Education Madeline Will issued a white paper on the REI (Will, 1986). The message of the white paper was clear: too many SE students were receiving services outside of their GE classes. The paper called for more collaboration between special and general educators and greater efforts to educate SE students in GE. Since that time, increased attention to outcomes and accountability for SE students relative to the GE curriculum has been incorporated in the Individuals with Disabilities Education Act (1997).

Both historical and current legal parameters affect reintegration decision making. From a historical perspective, the Least Restrictive Environment (LRE) clause of IDEA indicates clearly that students should be educated in the GE environment to the *maximum extent appropriate*. Specifically, the clause states:

> ...to the maximum extent appropriate, children with disabilities, including children in public or private institutions or other care facilities, are educated with children who are not disabled, and special classes, separate schooling, or other removal of children with disabilities from the regular educational environment occurs only when the nature and severity of the disability of the child is such that education in regular classes with the use of supplementary aids and services cannot be achieved satisfactorily. (Section 612, (a)(5)(A) IDEA, 1997).

This clause has been present since the inception of the Education of the Handicapped Act (EHA), with relatively minor changes in wording since that time. The one noticeable change is the addition of the words "special classes." Central to reintegration are the LRE concepts of "benefit" and "satisfactory achievement." These concepts were operationalized by the United States Supreme Court in *Hendrick Hudson District Board of Education v. Rowley* (1982). Benefit was defined as satisfactory achievement in GE. Satisfactory achievement was defined by the grading and achievement standards within the mainstream GE setting. Finally, recent changes in IDEA have reinforced greater attention to SE students' access to GE (Section 601 (c)(5)(A), IDEA) as well as measuring goals and objectives with the same frequency as GE (Section 614 (d)(1)(A)(vii)(II), IDEA).

Despite its clear importance, barriers to reintegration exist. First, SE typically has operated within a traditional deficit-centered model in which problems (disabilities) are viewed as relatively intractable or organic in nature. Framing problems in this manner reduces the likelihood that one would expect the student to exit SE. Another concern with this model includes the measures used for decision making. These measures often are focused on identification of student deficits and generally are not designed to contribute significantly to the development of effective interventions (Deno, 1986; Gresham & Witt, 1997; Marston, 1989; Shapiro, 1996a). The tools used to identify and re-evaluate students for SE often are not related closely to the GE curriculum or local GE standards. Instead, the measures often used are nationally normed achievement tests tied to globally derived national achievement standards. While useful for comparing students to a national standard, the tests may have little overlap with the local curriculum, often have few items at any particular grade level, and are not designed for sensitivity to individual student progress (Marston, 1989). Thus, such measures do a poor job of determining whether a student can meet the grading and achievement expectations in their local GE environment.

Another barrier occurs when parents and teachers are unwilling to return students receiving SE services to the GE environment (Fuchs, Fuchs, & Fernstrom, 1992; Shinn, Baker, Habedank, & Good; 1993; Weintraub, 1991). For the most part, reintegration decision making has relied heavily upon the volunteerism or "goodwill" (Fuchs et al., 1992) of teachers and parents. That is, all parties involved must be "willing" to participate in and agree to the decision to return a student to the GE classroom. If any of the individuals disagrees with a change in placement, the likelihood of the student being reintegrated is reduced greatly. The attitudes of parents and teachers regarding reintegration may reflect naiveté regarding the purpose of SE as a *supplement to* rather than a replacement for GE. Parents of students identified through traditional models of practice may view reintegration efforts as a reduction of SE services that are necessary to "maximize" their child's educational potential (Green & Shinn, 1994). In this era of high stakes testing and use of test scores for accountability, teachers may be concerned about the reintegrated student no longer receiving test accommodations that typically would be part of their IEP. Thus, unwillingness of parents and teachers may reflect anxiety about the impact of reintegration.

Special education teachers may be concerned about how their students will perform once reintegrated. General education teachers also may be reluctant to have SE students returned to their classes. Teachers may underestimate the academic and behavioral skill levels and progress of students receiving SE services. These concerns about reintegration can be remedied. For example, research (e.g., Rodden-Nord, Shinn, & Good, 1992; Shinn et al., 1993) suggests that teachers become more willing to reintegrate SE students when they are given data indicating that the student performs within the grading and achievement expectations of their GE classrooms. However, parents' willingness to reintegrate their child may be more dependent upon subjective factors rather than student performance data. For example, parents may rely heavily on SE teachers to interpret results and to make recommendations for reintegration (Ball, 1997; Green & Shinn, 1994).

Within a problem-solving model of practice, the collaboration between GE and SE teachers and parents from the onset of the process helps reduce misconceptions about the purposes of special education. School psychologists need to give due consideration to the concerns of parents, teachers, and other educational personnel so they can support reintegration decisions more adequately. Further, school psychologists need to be involved in staff-development efforts aimed at increasing skills related to reintegration success, and in making decisions about GE class placement on a more regular basis.

When Reintegration Should Be Considered

School psychologists should consider reintegration and possible exit from SE as a natural part of SE service provision. When the concerns that resulted in these services no longer warrant them, then reintegration is appropriate. For example, if a student's skills or behavior fall within the range acceptable in GE, then that student may no longer *need* SE services and reintegration should be considered. The question becomes, then, how does one know that skills and behaviors fall within an acceptable range?

BASIC CONSIDERATIONS

To make reintegration a reality, school psychologists need to have an understanding of the principles or values upon which the best practices described in this chapter are founded. These foundational principles are not connected to a specific technology or technologies. Thus, as technology improves or changes, these principles serve as a means of judging whether new technology serves the same purpose (Grimes & Tilly, 1996; Tilly & Grimes, 1998; Tilly, this volume). These guiding principles are as follows: (a) hypothesis testing, (b) formative evaluation/ongoing progress monitoring, (c) consideration of the classroom and school ecology, (d) case-by-case decision making, and (e) consideration of legal parameters.

Hypothesis Testing

Hypothesis testing is an integral part of the problem-solving process. One cannot know a priori that an intervention will be successful for an individual child (Campbell, 1988; Deno, 1986, 1989). School psychologists must recommend interventions, ensure they are implemented with integrity, and measure their effectiveness. In this way, interventions are considered hypotheses to be tested. The same notion applies to reintegration. Previous research (e.g., Shinn, Powell-Smith, Good, & Baker, 1997) suggests that reintegration trials be treated as hypotheses to be tested. Some students have responded well to reintegration while others with similar problems did not. The variables that determined the success or failure of reintegration were not apparent beforehand. Without collecting data during the reintegration trial period, the success of reintegration would have been ambiguous. Therefore, it is clear that hypothesis testing is tied closely to the process of formative evaluation and ongoing progress monitoring.

Formative Evaluation/Ongoing Progress Monitoring

Formative evaluation has two primary characteristics. The first of these characteristics is consistent with the rationale for hypothesis testing; that is, our interventions must be tested to determine their effectiveness. Second, formative evaluation involves examining student performance over time on a frequent and routine basis (Witt, Elliott, Daly, Gresham, & Kramer, 1998). "The emphasis in formative evaluation is on responsive, data-based problem-solving rather than on static diagnosis and prescription" (Deno, 1990, p. 169). This second characteristic suggests that data are collected for the purposes of making decisions about student performance and adjusting programs in a timely fashion. Thus, the purpose of formative evaluation is in direct contrast to the notion of diagnosing a problem for which one can then prescribe a specific treatment with a known outcome.

With regard to reintegration, formative evaluation is particularly important. Studies on reintegration efforts thus far (e.g., Shinn et al., 1997) suggest that the success of reintegration trials could not be predicted with 100% accuracy based upon data gathered prior to reintegration. Thus, ongoing monitoring of student performance is necessary once reintegration occurs to ensure success and modify services as needed.

Consideration of Classroom and School Ecology

Part of a problem-solving orientation is the consideration of variables that influence educational outcomes beyond those that are child-centered. A student's academic performance depends on multiple variables other than just student academic skill. School psychologists should be well versed in assessing components of instructional environments that facilitate or impede student learning or behavioral progress (Ysseldyke et al., 1997). Environmental factors such as "the nature and quality of teacher-student interactions, curricula, and materials also affect academic outcomes" (Fuchs, Fernstrom, Scott, Fuchs, & Vandermeer, 1994, p. 11). Classroom organizational structure and the diversity of students present also contribute to classroom and school ecology (Walker & Bullis, 1990). According to Witt et al. (1998), two fundamental assumptions of assessment are (a) that "individual differences among children derive their meaning from the situation in which they occur" (p. 7) and (b) "good assessment involves gathering information about the environment in which the student is functioning" (p. 12). Logically then, consideration of classroom and school ecology is an important part of any problem-solving process including reintegration.

Case-by-Case Decision Making

The notion of case-by-case decision making is associated with the *Responsible Reintegration* model delineated by Douglas Fuchs (Fuchs et al., 1992). This model specifies that students be considered for reintegration on an individual basis according to their unique skills and needs. Furthermore, such an approach dictates that the outcomes of reintegration be monitored to determine the effects, both short-and long-term, for the individual student. Thus single-case, rather than group analyses, are most appropriate for evaluating reintegration decisions. Case-by-case decision making also is in direct contrast to large-scale decisions, in which groups of students are reintegrated (i.e., all students with mild disabilities). As noted by Fuchs et al., a case-by-case approach is consistent with procedures set forth in federal law (e.g., IDEA) and, more importantly, with the recent legal parameters noted in the next section of this chapter.

Considering Legal Parameters

In a problem-solving system, a problem is defined by a discrepancy between what is expected and what is occurring (Deno, 1989; Shinn, 1995). Professional judgment helps determine the standard against which student performance is judged to be problematic (Tilly, this volume). However, when it comes to reintegration and exit decisions, the U.S. Supreme Court has determined the performance standard against which a student's appropriateness for GE is judged. If a student can perform within the grading and achievement standards for GE, then that student should be educated in that environment (*Hendrick Hudson District Board of Education v. Rowley*, 1982).

Several court cases have examined this issue. Specifically, three standards for determining LRE have been yielded from recent circuit court decisions. The 3rd, 5th, and 11th circuits have adopted the Daniel R.R. test. This test determines if education in the GE classroom with the use of supplemental aids and services can be achieved satisfactorily and if the school has mainstreamed the child to the maximum extent appropriate. The following four issues are examined: (a) the steps a school has taken to accommodate the child in the GE classroom, (b) the educational benefit the child will receive from placement in the GE environment, (c) the child's overall educational experience in GE, and (d) the effect that the presence of the child with the disability has on the peers in the GE classroom (*Daniel R.R. v. State Board of Education*, 1989). Decisions in the Greer and Oberti cases in the 11th and 3rd circuit courts modified the Daniel R. R. test to allow a comparison of the benefits of GE versus SE (*Greer v. Rome City School District*, 1991; *Oberti v. Board of Education of Clementon School District*, 1993).

As another example, the 4th, 6th, and 8th Circuits have adopted the Ronker Test (*Ronker v. Walter*, 1983). For this test, the courts ask whether services in a segregated setting can be provided feasibly in a non-segregated setting and consider the following: (a) the benefits the child receives from an SE class compared to those in GE, (b) whether a child with a disability would be disruptive in the GE class, and (c) the cost of maintaining the child in GE. Finally, the 9th Circuit has used a test that applies both the Daniel RR and Ronker tests. For this test the court considers: (a) the educational benefits of full-time placement in a GE class, (b) the non-academic benefits of such a placement, (c) the effect the student has on the teacher and children in the GE class, and (d) the costs of mainstreaming the student (*Sacramento Unified School District v. Rachel H.*, 14 F.3rd 1398, 1404, 1994).

In addition to being knowledgeable of recent LRE court decisions, school psychologists must understand clearly that IDEA and recent case law do not support *maximizing* the potential of each child with a disability. Rather, the judgment in the Rowley case clearly states that education must provide services "sufficient to confer some educational benefit upon the handicapped child" (*Hendrick Hudson District Board of Education v. Rowley* p. 200). However, "the furnishing of every special service necessary to maximize each handicapped child's potential" (p.199) is not required by IDEA. Consistent with Rowley, the 4th circuit, in its opinion in *Hartmann v. Loudoun County Board of Education* (1997), indicated that IDEA does not guarantee every child with a disability the ideal educational opportunity. School psychologists must be facile with these rulings because they may be unfamiliar to key people (e.g., parents and teachers) involved in reintegration decision making.

A misunderstanding of the purpose of SE also may exist. The purpose of SE is to provide a *free appropriate public education* (FAPE), not to maximize a child's potential. A lack of understanding of "sufficient" versus "maximum" educational benefit may cause concern when considering reintegrating a student into the low achieving group of GE peers. People may fear this standard is too low, despite the fact that it is acceptable within the grading and achievement expectations in GE. Importantly, this standard should not be construed as reinforcing lowered expectations for children with disabilities. However, to withhold the opportunity for instruction in GE because the child does not meet at least average expectations may prevent further acceleration of their skills and limit their future opportunities.

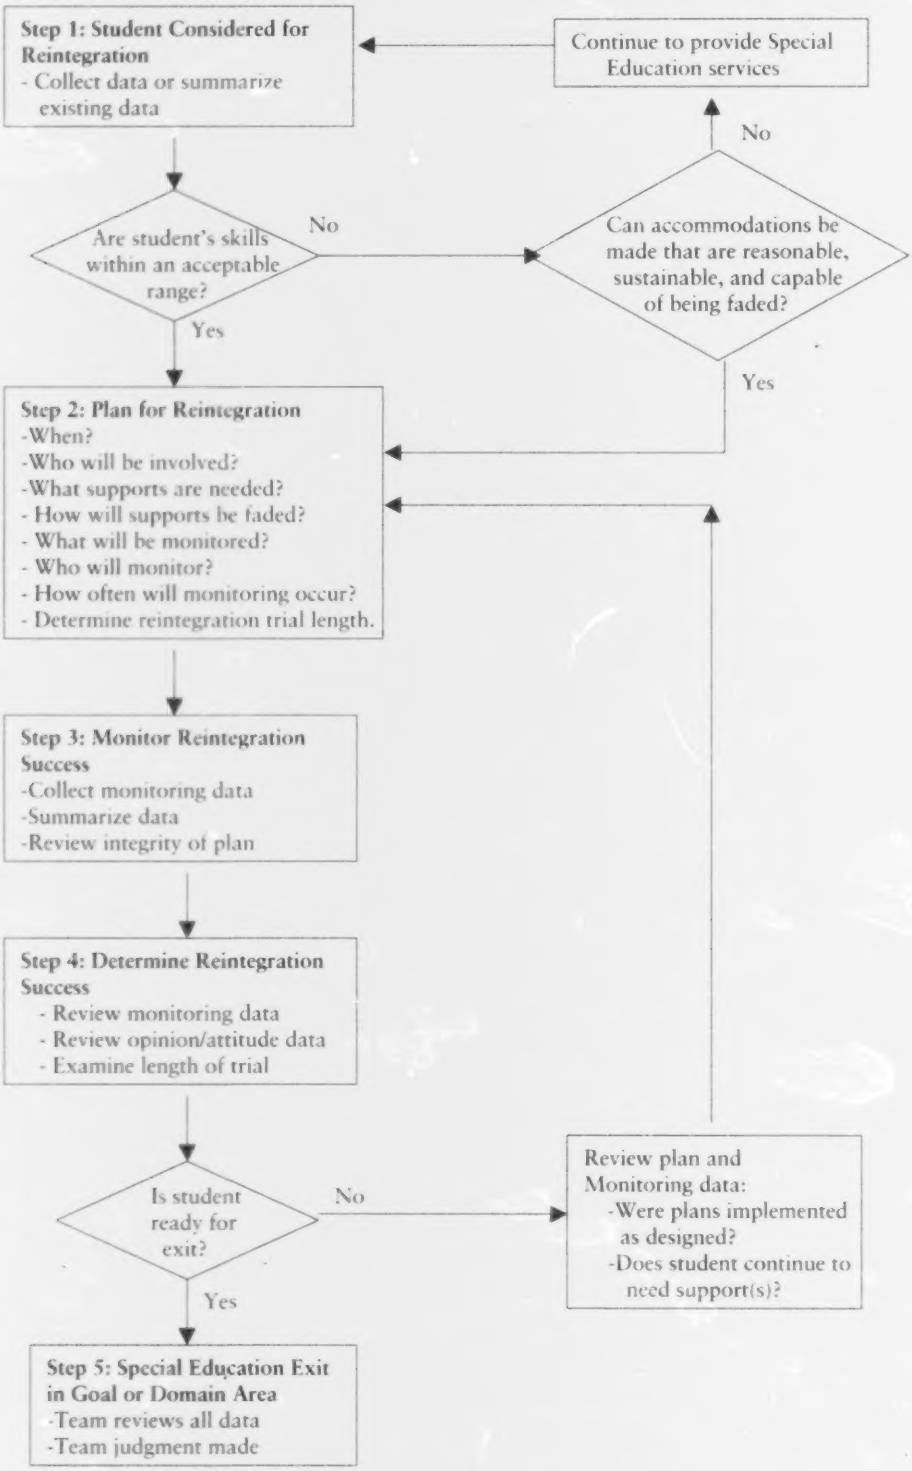
BEST PRACTICES

Within a problem-solving model of practice, students are identified for SE services because of a mismatch or a discrepancy between their current performance and what is expected of them (Deno, 1989; Shinn,1995). *Problem identification* begins with data-collection activities that focus on functionally relevant behaviors of concern (e.g., fluency in reading decoding, accuracy of math computation, level of academic engagement, frequency of behavioral outbursts). The purpose of problem identification is to measure and define the significance of a discrepancy. The data collected help substantiate the significance of the discrepancy and contribute to the diagnosis of the problem (*problem analysis*). Hypotheses generated from the assessment data and from problem analysis lead to the selection and implementation of interventions that have the highest probability of reducing the discrepancy between the target student's performance and GE expectations. Goals and interventions needed for the student to achieve satisfactorily compared to the typical students' performances are discussed (i.e., *intervention planning and goal setting*). *Progress monitoring* of the student's achievement occurs over an agreed upon period of time. Finally, intervention effectiveness is evaluated at the end of the progress-monitoring period (i.e., *program evaluation*) by collecting data to determine whether a significant discrepancy still exists.

In a problem-solving model, reintegration decisions flow naturally from the activities involved in progress monitoring and program evaluation. Best practices in reintegration and exit decisions within a problem-solving model incorporate provisions for exit that are discussed at the time of initial identification. At that time, outcomes for the student are discussed with an eye toward eventual reintegration and exit. For example, the skills and behaviors needed to be successful in the GE environment are discussed. As teams meet to develop an IEP and more long-range plans (5 years or more), they would conduct their planning with the notion that reintegration, whether in a single domain or across all domains, is a potential goal. Relevant areas to consider might include: cognition; achievement; social, behavioral, and emotional adjustment; communication and language; sensory status; motor skills; and health status. Consistent with the problem-solving process, at each checkpoint the student's progress relative to reintegration and exit is discussed, whether it is at the end of the grading period, annual review, 3-year review, or during transition planning. Reintegration and exit may not be a realistic or appropriate goal in all domains for all students receiving SE services. However, reintegration should be discussed at the time of identification if there is to be any chance of it occurring in a systematic manner.

The reintegration and exit processes outlined in this chapter follow a series of steps consistent with a problem-solving model. These steps also are consistent with the foundational principles outlined at the beginning of this chapter. Specific questions and activities are delineated at each step of the process (see Figure 1). Step 1 begins the process with the student being considered for reintegration, followed by planning for reintegration (Step 2), monitoring reintegration success (Step 3), determining reintegration success (Step 4), and exiting SE in the goal or domain area (Step 5). Any person involved in the student's education (parent, GE teacher, SE teacher, principal, counselor, and/or school psychologist) could prompt a closer look at reintegration at any time. Most typically, the timing of these decisions would be at the natural decision-making points for student evaluation (e.g., interim reporting, quarterly grading periods, annual review).

Figure 1. Reintegration and exit process, specific steps, and activities for each step



Step 1: Student Considered for Reintegration
- Collect data or summarize existing data
Continue to provide Special Education services
No
Are student's skills within an acceptable range?
No
Can accommodations be made that are reasonable, sustainable, and capable of being faded?
Yes
Yes
Step 2: Plan for Reintegration
-When?
-Who will be involved?
-What supports are needed?
- How will supports be faded?
- What will be monitored?
- Who will monitor?
- How often will monitoring occur?
- Determine reintegration trial length.
Step 3: Monitor Reintegration Success
-Collect monitoring data
-Summarize data
-Review integrity of plan
Step 4: Determine Reintegration Success
- Review monitoring data
- Review opinion/attitude data
- Examine length of trial
Is student ready for exit?
No
Review plan and Monitoring data:
-Were plans implemented as designed?
-Does student continue to need support(s)?
Yes
Step 5: Special Education Exit in Goal or Domain Area
-Team reviews all data
-Team judgment made

Step 1: Student Considered for Reintegration

In systems not currently operating within a problem-solving paradigm, reintegration decisions continue to be necessary and feasible. However, within these systems, reintegration and exit issues are more challenging. Data collected for eligibility and placement decisions typically do not link to goals and effective interventions. Eligibility test data are primarily administrative and procedural in purpose rather than functional and diagnostic. "Attempting to 'link' administrative assessment strategies to the development and evaluation of interventions is problematic" (Batsche & Knoff, 1995, p. 570). Thus, additional data similar to those collected within a problem-solving model must be obtained to facilitate reintegration and exit decision making. The relevant questions continue to be whether the target student is making adequate progress in comparison to GE peers and whether there has been a significant decrease in the discrepancy that resulted in SE service provision. Answering these questions requires obtaining samples of the academic and/or behavioral skills of the identified student and of the comparison students within the receiving GE classroom.

ACADEMIC SKILL DOMAINS

When considering academic skill domains, examining the performance data of the target student and the typical GE peers may be multifaceted. First, we could access existing achievement data typically collected by schools or districts. Second, we could sample directly the academic skills of the target student and comparison peers in the receiving reintegration classroom. Finally, we could interview the receiving GE and SE teachers and observe in the environment of interest to determine which academic survival skills are needed within the reintegration environment.

Schools often assess student achievement and compile the results using multiple methods. These data can be examined for performance trends between districts, buildings, and classrooms. For example, assessments may include state proficiency tests, standardized achievement tests, competency-based evaluations, portfolios, performance-based projects, Curriculum-Based Measures (CBM) (Deno, 1985; Shinn, 1989), and Dynamic Indicators of Basic Early Literacy Skills (DIBELS) (Kaminski & Good, 1996, 1998). Standardized proficiency and achievement tests are less direct measures of the behaviors of concern in the classroom. However, the information obtained may help to define performance discrepancies. The definition of average or below average achievement is a local district decision. For example, some districts may consider students performing below the 25th percentile to be at risk for academic failure. Other districts may recognize the 16th or 10th percentile ranks as the cut off for defining children who are in need of additional resources. Conversely, a district may consider students to have average skills if their reading and math scores on a standardized achievement test range from the 16th to the 84th percentiles. Some district personnel may discuss these issues in terms of the degree to which students meet grade level expectations. For other districts, no formal definition may exist.

Once a school psychologist determines the district's definition of average, low average, and below average achievement, it is possible to analyze data from various achievement results by grade level or by classroom. Comparisons of the target student's performance to that of typical peers may indicate a significant discrepancy on various achievement measures that are collected school or district-wide each year. A more direct and functional assessment of basic academic skills would include CBM or DIBELS collected at the individual classroom, building, or district level. CBM of reading, math, spelling, or written language and DIBELS measures provide excellent comparison data and when normed at the district or building level may include percentile ranks or median scores by grade level or by classroom.

In addition to reviewing existing data, direct assessment of the target student's academic skills in comparison to students in the receiving reintegration classroom will be necessary. The dimensions of comparison are determined by the behavior(s) of concern and the instances in which the target student will be required to use the skill. For example, many students receiving SE services have reading skill deficits that affect numerous areas of performance in the classroom. A comprehensive assessment for a student considered for reintegration would include basic reading fluency and comprehension of the GE language arts curriculum. However, because reading ability effects numerous other academic tasks, it is necessary to assess the student's application of reading to successfully complete in-class assignments and homework, as well as other academic course work (e.g., math, science, social studies).

In all instances, the performance of the target student is compared to the expectations in the reintegration environment, defined by the performance of GE peers. Collecting local classroom-norms offers a viable method by which to obtain this comparison. A classroom norm is obtained by asking the receiving teacher to nominate five to seven students who perform at the lowest acceptable level in the GE classroom. Next, the students nominated for the micro-norm and the target student are assessed across academic behaviors of interest, using the same measurement tools. For example, several previous studies have demonstrated the utility of using CBM for these purposes (see Powell-Smith & Stewart, 1998, for details). The median or average results of the typical students' academic performance on any given academic behavior provide the micro-norms to which the target student's performance is compared. The overall task is to determine if the target student is performing academically within the range of students in GE. If the student considered for reintegration is successful on tasks performed within lowest acceptable performing instructional group, then that instructional setting may represent the LRE for the student. If the target student continues to demonstrate a discrepancy in performance, consideration should be given to the accommodations and supports in the reintegration classroom that would allow the student to be successful. If the student exhibits discrepancies that are so significant that accommodations and supports would be beyond what GE could provide, then reintegration may not be an option.

Beyond examination of the target student's specific academic skill development, other considerations may include the academic survival skills necessary to be successful in the reintegration environment (e.g., academic-engaged time, organizational skills, self-management strategies, and study- and test-taking skills). Information about academic survival skills may be obtained by observing the behaviors of the local normative group and the target student. This task may be difficult if the student considered for reintegration receives services in an SE pull-out program. However, even within a smaller teacher/student ratio, these behaviors would be present and observable. It also is possible to have a trial reintegration period with the intent of collecting data in the most natural environment possible.

Finally, teacher interviews may be conducted to obtain information about the target student's skills as well as the expectations in the reintegration environment. The SE teacher will have valuable information about the student's specific academic skills, rates of attention and academic engagement, work completion and accuracy rates, and self-management strategies (i.e., academic task-related behaviors). An interview with the GE teacher would provide information about the academic task-related behaviors expected in the GE environment. School psychologists may have formal or informal interview methods by which to gather this information. The interview should focus on the teacher's expectations for academic task-related behaviors from students throughout each instructional period and during alterations in the schedule and daily routines (e.g., substitute teachers, assemblies, guest speakers). School psychologists may choose to review the literature and programs available to organize and structure a teacher interview (e.g., Kame'enui & Darch, 1995; Paine, Radicchi, Rossellini, Deutchman, & Darch,1983; Sprick, Garrison, & Howard, 1998). The interview could, in turn, assist school psychologists and teachers in designing classrooms that help students meet the expectations in a variety of environments. Teachers who clarify their expectations for student success during the instructional day may have better-managed classrooms. In turn, a well-managed classroom may be the most appropriate reintegration setting for a student, depending on the reasons for SE placement.

BEHAVIORAL AND OTHER CONCERNS

The questions to consider in making reintegration decisions for students receiving SE services for behavioral, social-emotional, communication, and other concerns, are similar to those for a student receiving SE services for academic concerns. The standard for when to consider reintegration remains the same; reintegration should be considered when the student can meet not only the grading and achievement expectations for GE, but also the behavioral and social-emotional requirements to be successful in the GE environment. The goal is to determine what the grading and achievement expectations are with respect to behavior and social-emotional functioning for the GE environment.

Several variables might be examined to determine if the student meets GE environmental expectations for behavior and social-emotional functioning. These variables include those that are student focused such as coping strategies, teacher pleasing behaviors (e.g., follows directions, accepts consequences, listens), self-help and problem-solving skills (e.g., works independently, makes need for assistance known, controls anger), and positive peer interactions (e.g., cooperates with others). Other variables include those that are more teacher focused, such as tolerance for student misbehavior, teacher attention, motivational procedures, classroom management practices. Finally, specific classroom environment variables to consider include: (a) classroom organization and routines, (b) instructional arrangements, (c) classroom physical arrangement, (d) number and length of transitions, and (e) the involvement of others (e.g., paraprofessionals, support specialists) in the classroom.

Obtaining information about the normative expectations for student behavior is accomplished best through direct observation techniques. School psychologists can choose from a number of published behavioral observation codes such as the Code for Instructional Structure and Student Academic Response (CISSAR; Stanley & Greenwood, 1981), the State Event Classroom Observation System (SECOS; Saudargas, 1992), and the Behavioral Observation of Students in Schools (B.O.S.S.; Shapiro, 1996b). School psychologists also could develop their own behavior observation code. Should school psychologists choose to develop their own code, they may want to consult published resources (e.g., Alessi & Kaye, 1983; Cooper, Heron, & Heward, 1987; Hintze, this volume) for ideas about how to develop useful and reliable protocols to document students' behavior within various instructional environments.

To determine what the normative expectations are for the receiving GE environment, the school psychologist would observe students in the classroom (or classrooms) that represent the lowest *acceptable* standard for behavioral and social-emotional functioning. The school psychologist should consult with the teacher(s) in those classrooms to determine who these students are. In keeping with the lowest *acceptable* level as the standard, students chosen for observation should not be ones considered at-risk for referral for behavioral or social-emotional concerns. Neither should they be students considered model classroom citizens. Multiple observations using the same instruments for both target student and comparison peers should occur in the receiving classroom(s). Ideally, observations should be made across several days and times to see the range of the student behaviors and to increase the reliability and accuracy of the information. Observations should occur during structured academic periods (e.g., reading, math, science) and during less structured academic periods (e.g., art, P.E., music). Direct observations also should be conducted while students are in hallways, on the playground, and in the cafeteria where many student misbehaviors occur. Information on the range of behaviors acceptable within the school at large will help to successfully reintegrate students who have difficulties with self-managing behavior. From these observations, local micro-norms for behavior can be developed (see Alessi & Kaye, 1983; Canter, this volume). Once these micro-norms are developed, the data collected on the target student's behavior across a variety of settings can be compared to those norms to determine if his/her behavior falls within an acceptable range. A concern with this process is that the reintegration candidate may not be observed in the exact same settings and under the same conditions as the GE comparison group. However, these data will provide some basis for comparison. When combined with other data, these data should contribute significantly to reintegration decision making. Notably, similar procedures can be used for examining reintegration for students with concerns in other domains (e.g., communication/language).

Another important task for determining a student's appropriateness for reintegration is obtaining information about GE teacher expectations and classroom environmental variables. Direct observation and teacher interview are the two best methods for examining these variables. School psychologists could use narrative direct observations to examine the natural flow of classroom events as well as how transitions are managed. During observations, school psychologists can observe classroom management techniques such as posted rules and schedules, reinforcement and feedback for rule-following, length of transition times, management of mild disruptive behaviors, etc. Again, published observation codes can be used to examine these variables such as the Classroom Ecological Inventory (CEI) Classroom Observation (Fuchs et al., 1994), the Instructional Environment Scales (TIES) (Ysseldyke & Christenson, 1987), the CISSAR, and the SECOS. Alternatively, school psychologists may choose to develop their own observation code.

Teacher interviews can be used by school psychologists to obtain information about classroom environment, teachers' motivational strategies, classroom rules, allocation of instructional time, as well as information about teacher tolerance for mild disruptive behavior. School psychologists could use questions from published interview formats such as: (a) CEI Teacher Interview (Fuchs et al., 1994), (b) the TIES, (c) the Teacher Interview Form for Academic Problems (Shapiro, 1996a), and (d) the Instructional Planning Form Interview (Powell-Smith & Stewart, 1998). School psychologists also can create their own set of interview questions based upon review of the literature on programs that emphasize proactive classroom management and instructional techniques (see Kame'enui & Darch, 1995; Paine et al., 1983; Sprick et al., 1998). School psychologists also can take advantage of published resources regarding interviewing procedures in general (e.g., Bergan & Kratochwill, 1990; Lentz & Wehmann, 1995). Again, the purpose of observations and interviews is to determine the discrepancy between the potential receiving GE classroom and the SE classroom. The degree of discrepancy along with the student behavioral observation data serves as the basis for making reintegration decisions. Ultimately, the team of individuals responsible for reintegration decisions will need to determine the behaviors and skills to be examined for the individual student's reintegration to be successful. Resources related to assessment and progress monitoring of student performance are provided in the reference and annotated bibliography section of this chapter and in Tilly (this volume).

Once Step 1 of the process is completed, possible decision outcomes include the following: (a) reintegrate and monitor; (b) reintegrate and provide training, support, and monitoring; or (c) wait on reintegration until the match between the student's skills and the demands of the environment are aligned more closely. Both outcome (a) and outcome (b) would occur at Steps 2 and 3 of the reintegration and exit process. As evident by outcome (c) the activities involved in this process will cause special education and student services personnel (e.g., school psychologists) to examine more closely the kinds of training and supports necessary to achieve reintegration. These supports might include: working with GE teachers to increase their classroom management skills, working with SE teachers to incorporate more of the elements found in the GE classroom into the SE classroom (i.e., training for generalization), and/or training the individual student in the skills needed to be successful in GE. Ultimately, this process forces a discussion of reintegration issues and allows for greater collaboration and communication between SE and GE.

Step 2: Plan for Reintegration

Once the reintegration and exit process moves to Step 2, the tasks are essentially the same in systems using traditional SE identification practices as well as those used in school systems using a problem-solving model. These tasks include: determining which team members are needed for planning, when reintegration should occur, measures to be implemented and frequency of progress monitoring activities, person(s) responsible for measurement activities, supports and accommodations that are necessary for success, length of the reintegration trial, and techniques for eventually fading the plan and supports (see Figure 1).

The reintegration planning team includes those individuals who have direct knowledge of the target student's current academic skills and behavioral status and anyone who may instruct the child in the new class. Teams should include the parent(s) of the student, the SE teacher, the receiving GE teacher(s), and the student, if appropriate. Teams also may include paraprofessionals, administrators, and support staff (e.g., school psychologist, speech pathologist, behavior intervention specialist, etc.). If the student is involved with outside agencies (e.g., mental health provider, medical personnel, social worker, case manager), it may be appropriate to invite representatives to attend the planning meeting(s) to coordinate services.

Reintegration may occur as soon as the team's reintegration plan can be implemented. It is possible that the student could be placed immediately into the GE environment for the domain considered. In other cases, the student might be introduced to the new environment gradually. For example, the plan may call for the student to be involved in only a portion of a class (e.g., group discussion, teacher-led instruction, pre-writing activity). The student might then receive assistance from a SE support person or a paraprofessional to complete the required assignments. Over a period of time, the student's involvement in the GE class would increase as the student increases timely work completion and accuracy. Another example involves the student reintegrated into a GE class with adequate skills to complete assignments, but lacks behavioral strategies to follow rules, remain academically engaged, interact with peers appropriately, etc. This student's plan may call for reintegration in the receiving class with incremental increases in time being dependent upon the student's skills in maintaining appropriate behavior.

As stated in Step 1, the techniques needed to monitor student progress in the reintegration environment and the length of the trial period are based on the academic skills or behaviors of interest. These decisions will be based on research related to the target behaviors and professional judgment. For example, the literature on reintegration in reading indicates that a minimum of 8–12 weeks of CBM progress monitoring is recommended (Powell-Smith & Stewart, 1998). Ultimately, academic skills or target behaviors must be monitored over an appropriate time frame to determine the student's success or lack of progress within the new environment. The reintegration plan should include specific review periods at which time student performance data can be reviewed and alterations made in the plan if needed.

As a part of the reintegration plan, it is appropriate that team members be assigned specific tasks to complete before the next review period. The plan should be clear regarding the exact measurement techniques to be used and the person(s) responsible for data-collection activities. Team members should be willing to step outside their traditional roles to support the success of the reintegration plan. For example, paraprofessionals and school psychologists are excellent members to support data collection efforts. Any training needs for personnel unfamiliar with data collection techniques should include follow-up support and reliability checks to ensure treatment integrity. Timelines for plan implementation and data collection should be specific with agreed upon review dates set in advance.

Modifications of the reintegration plan may occur, if necessary. The planning team should meet at periodic intervals to review and document the progress-monitoring data and to consider the accommodations and supports necessary for student success. Many modifications may mirror those that are typical for all students. For example, repeating directions, additional time for task completion, adjusting task length, frequent prompts and feedback, mass practice of skills, and individual or small-group instruction from teacher, paraprofessionals, or Title I teachers, all may be possible accommodations. Considering supports that occur naturally within GE will help the student generalize and maintain skills after the reintegration plan is faded. Modifications must be *documented* so that the team can determine the types and levels of support necessary for a student to succeed. This documentation coupled with progress monitoring data also allows the team to determine if and when support can be faded should the target student demonstrate significant progress in the new environment. Conversely, if documentation demonstrates that the levels of accommodations and supports are so significant that GE cannot sustain them, then the student may not be ready for reintegration.

Step 3: Monitor Reintegration Success

Once the reintegration plan is completed, it is necessary to begin the trial reintegration period and the data collection activities delineated in Step 3. Determination of reintegration success will be based on the results of both direct and indirect data collection methods. Direct data collection procedures will include assessing the target student's academic achievement and behavior through progress monitoring activities specified in the plan. Also, plan implementation integrity will be monitored through direct observations of intervention adherence. The measures of treatment integrity may indicate that additional training is necessary for participants to successfully carry out their responsibilities as the plan indicates.

Indirect measures of the plan's success may include questionnaires about participants' level of satisfaction with the reintegration plan, the interventions, and the training and support for implementation and data collection. It also will be important to survey attitudes of parents, the reintegrated student, general and special education teachers, and paraprofessionals about the success of reintegration trial (see Powell-Smith & Stewart, 1998, for examples). School psychologists can play a vital role in providing the training for progress monitoring, assessing treatment integrity, and in developing surveys that assess participant satisfaction with the reintegration process.

Step 4: Determine Reintegration Success

After the reintegrated student has been monitored for the length of time specified in Step 2, a determination about the success of reintegration can be made. All monitoring data collected up to that time are examined along with data collected on teacher, student, and parent attitudes toward the reintegration. The monitoring data are important because they provide both formative and summative information about the impact of reintegration on the student's skills. From these data, we can examine whether the student's progress is commensurate with that of the GE peer comparison group. Parent and teacher attitudes are important to gauge because their involvement in the process is consistent with best practices. Also, their attitudes may present possible barriers to continued reintegration efforts. Student attitudes are important to assess as they also may influence the success of reintegration efforts (Powell-Smith & Sheble, 2001). The length of the reintegration trial also should be examined.

Finally, the question of whether the student is ready to exit SE is asked. No set timeline for making such decisions exists because there is very little research in this area. Clearly, this decision should be based upon the data gathered and professional judgment. If the answer to the question is yes, then we proceed to Step 5. If the answer is no, the process cycles back to Steps 2 and 3 to review the initial reintegration plan, determine if plans were implemented as designed, and re-examine the monitoring and attitude survey data collected. A critical question at this point is, does the student still need support(s)? If the answer is yes, the team needs to make the necessary modifications to the original plan developed at Step 2. Once the modified plan is implemented, the process moves to Step 3 and so on.

Step 5: Special Education Exit in Goal or Domain Area

Step 5 is the culminating activity in the reintegration process. At this point, the team has reviewed the data and decided that SE exit in the goal area(s) or domain(s) for which the child was reintegrated is appropriate. This decision involves professional judgment based upon the preponderance of the data. Not all students will progress to Step 5 (e.g., those with more significant disabilities, those that began much farther behind). Some students may need greater support in content areas or upon reaching middle or high school. Also, there is no reason a student could not be considered again for SE services should they become necessary in the future. However, these steps are designed to preserve the SE continuum, while forcing a closer examination of LRE and exit decisions.

SUMMARY

Reintegration is a process by which students receiving SE are returned systematically to the GE environment for instruction. The process is not to be equated with "mainstreaming" or "inclusion," both of which indicate that students continue to need SE services. Rather, candidates for reintegration are those students who originally were identified as needing special services, but no longer demonstrate large gaps in their academic skills or behavioral repertoire. In other words, the problem(s) that resulted in SE placement no longer warrant SE services. These students may be appropriate for instruction in the same environment as their GE peers, with the eventual possibility of exiting SE on a permanent basis.

Considering SE students for reintegration is no longer an afterthought, but rather is an integral part of the IEP process and service delivery. Neither is reintegration an all or nothing decision. It is a process that is accomplished by determining the LRE for students on a case-by-case basis. This single subject model of examining a student's appropriateness for reintegration results in the most appropriate educational decisions for individual children.

Planning for reintegration of a student occurs at the onset of the IEP process. Implementing a trial reintegration plan is accomplished by incorporating a problem-solving framework that involves persons who are key to student success, identifies student needs and current levels of performance relative to those of GE peers, and makes data-based decisions about student progress on a frequent and repeated basis. If the data collected indicate that a student is successful according to the grading standards established in GE environments, then that class may represent the LRE for that student.

ANNOTATED BIBLIOGRAPHY

Kame'enui, E. J., & Darch, C. B. (1995). *Instructional classroom management.* White Plains, NY: Longman.

This book outlines an instructional approach to classroom management, a technique that emphasizes proactive teaching of expected classroom behavior. The impact of instructional task dimensions such as complexity, modality, and response form on classroom management is discussed along with how to integrate classroom management during each temporal phase of instruction. Assessment models, as well as chapters on reinforcement, punishment as a transition tool, and a three-phase implementation across a180-day school year, are presented. A procedural model for managing persistent behavior problems is also provided along with the features of an effective school-wide discipline policy.

Paine, S. C., Radicchi, J., Rossellini, L. C., Deutchman, L., & Darch, C. B. (1983). *Structuring your classroom for academic success.* Champaign, IL: Research Press.

This book outlines basic classroom management techniques including classroom organization, involvement of others in the classroom, use of teacher attention and classroom rules, managing materials and paperwork, and managing behavior problems. Feedback chart procedures for developing good work habits and guidelines for phasing out special procedures also are presented. The procedures are based on the Direct Instruction Model. The authors provide a survey of relevant research at the end of each chapter, as well as scripts that teachers can use to implement each technique.

Powell-Smith, K. A., & Stewart, L. H. (1998). The use of Curriculum-Based Measurement in the reintegration of students with mild disabilities. In M. R. Shinn (Ed.), *Advanced applications of Curriculum-Based Measurement* (pp. 254–297). New York: Guilford.

This chapter provides an overview of the Responsible Reintegration of Academically Competent Students (RReACS) model for students with mild disabilities, including the philosophical and legal foundations for the model and the incorporation of CBM in the six implementation steps. Research outcomes of RReACS, such as numbers of potential candidates for reintegration based on both nomothetic and idiographic approaches, teacher and parent attitudes toward reintegration, and student achievement outcomes also are presented.

Sprick, R., Garrison, M., & Howard, L. (1998). *CHAMPs: A proactive and positive approach to classroom management.* Longmont, CO: Sopris West.

The authors of this book present a research-based model

for classroom management for grades K through 9. The CHAMPs behavior program consists of eight modules, each representing a key aspect of effective classroom management: Vision, Organization, Expectations, the First Month, Motivation, Monitor and Revise, Correction Procedures, and Class-wide Motivation Systems. The modules include self-assessment tools as well as activities and discussion questions that can be used by teacher work groups. CHAMPs emphasize teacher expectations, and each letter in the acronym stands for a type of expectation that should be clarified for students: Conversation (can students talk?), Help (how do students request help?). Activity (what is the objective of the activity?), Movement (can students get out of their seats?), and Participation (how do students show they are participating?).

AUTHOR NOTE

The authors would like to express their sincere gratitude to Angela Sheble for her assistance with the annotated bibliography for this chapter.

37 Best Practices in Defining Student Goals and Outcomes

Lynn S. Fuchs
Peabody College of Vanderbilt University

OVERVIEW

The importance of goals in understanding human behavior is critical. Individuals organize their activities around sets of goals that relate to their current levels of performance and their aspirations, and the nature of an individual's goals and his or her daily strivings are intimately intertwined. In a similar way, schools are organized around sets of goals, which relate to age-appropriate societal expectations, and the nature of those goals and the curricula of schools, or what teachers teach, are inextricably connected. Clearly written justifiable goals and procedures for evaluating goal attainment are potentially key factors to successful educational programs. Over the years, the press to specify clear and measurable outcomes for individual students has increased dramatically. The purpose of this chapter is to discuss the history, context, purposes, and applications of goals and to present alternative methods for accomplishing the specification of useful, manageable goal statements.

History and Rationale

Prior to the turn of the twentieth century, psychologists viewed the brain as a composite of general intellectual faculties that, when strengthened, could be applied to any area of human activity. So, if educators identified faculties and strengthened them, they would expect concurrent educational growth. At the turn of the century, however, Thorndike demonstrated the specificity of transfer, such that learning occurs when elements in the original content are relevant and similar to elements in other contexts. Applying Thorndike's work to the development of educational curricula, Bobbitt (1918) argued that human life consists of the performance of specific activities, and the numerous skills and knowledge required for successful adult life should constitute the curriculum of schools.

Consequently, psychologists began to develop the notion that general intellectual growth might be operationalized into series of learning products. This premise was central to Ralph Tyler's work in curriculum and instruction. Tyler viewed evaluation as the demonstration of the ways and extent to which students have changed in relation to a set of desired outcome behaviors. While in charge of the 8-year study of secondary education for the Progressive Education Association, Tyler emphasized successfully the need to define educational goals in terms of student behaviors and specific content. A product of that study was Smith and Tyler's book, *Appraising and Recording Student Progress* (1942), which lists numerous behavioral objectives. In his role as director of the National Assessment Project, Tyler required that educational objectives constitute the groundwork for developing curriculum materials and instructional procedures and in designing evaluation instruments to appraise the effectiveness of these newly developed materials and procedures (Bloom, Hastings, & Madaus, 1971).

Psychologists such as Gagne, Glaser, and Mager also were interested in developing clear statements of educational objectives. In contrast to Tyler who was interested in evaluation, however, those investigators were interested primarily in the development of effective instruction. Their focus was on task analysis or the description of behavioral outcomes in terms of a repertoire of discrete behaviors that must be sequentially built to arrive at a terminal performance. The work of Gagne and others served to develop further the notion that school-related growth could be operationalized and segmented into very small units.

Perhaps one of the major impacts of the use of distinct behavioral objectives in schools was to render local educational agencies more accountable to the public for the content and effectiveness of their programs. Similarly, in special education, accountability was one of the important rationales for mandating the development of Individual Educational Programs (IEPs), which include annual goals and short-term objectives. Developers of PL 94-142 intended that the IEP statement of goals, along with procedures and criteria for determining whether goals are being met, would assure that schools were accountable to students, parents, and taxpayers for the quality of the programs they provided students with disabilities (Turnbull & Turnbull, 1978). Unfortunately, in the first two decades of P.L. 94-142's implementation, accountability focused almost exclusively on procedural compliance, or documenting that goals and objectives were written and that services were provided.

Current Context

In more recent years, as concern about this country's academic and workplace competitiveness has increased, the demand for accountability for student outcomes has increased within special education and spread across the entire educational system. In September 1990, President George Bush convened an historic education summit with the nation's governors at the University of Virginia, the only time in our country's history that such a summit has been held to discuss issues pertaining to education. In his concluding remarks, President Bush discussed the overwhelming need to establish "accountability for outcome-related results."

This distinction between procedural and outcome accountability is particularly relevant to special education. As stated, following passage of P.L. 94-142 in 1975, the field witnessed a 20-year focus on procedural compliance. In 1995, however, in synchrony with the accountability movement within general education, the field began to refocus attention on the question of what students are learning, rather than what services are being provided. As we entered the second half of the last decade of the century, when resources became tighter, when we increasingly began to compete economically in an international marketplace, and when the disparities between the wealthy and poor grew, accountability became the operant word for justifying increasing funds for schooling. The public required that schools demonstrate student improvement or results to justify increased expenditures, including funds for special education.

With the 1997 amendments to the Individuals with Disabilities Education Act, this focus on accountability for student outcomes became officially codified into law. All students with disabilities are now required to be included within general education accountability frameworks and to be included within all public reports of student outcomes. In addition, the focus on student outcomes, rather than on procedural compliance, within IEPs has become strengthened.

Purposes

As the press to account for the effects of schooling continues to mount, the critical issue is how to define our goals so they represent the most important outcomes for our students to achieve. In considering alternative methods for specifying our goal statements, three critical purposes for developing goals are relevant: (a) to direct teaching and curriculum development, (b) to guide learners, and (c) to structure evaluation and accountability.

DIRECTING TEACHING AND CURRICULUM DEVELOPMENT

Studies indicate that teaching with goals fosters student academic growth and teacher success. In an early study, for example, McNeil (1967) randomly assigned 77 university teacher trainees to two groups. In the experimental group, trainees contracted with their cooperating teachers for what student changes would constitute success; in the control group, practicing teachers familiarized themselves with class activities and prepared daily lesson plans. Both supervisors and cooperating teachers judged the experimental trainees as achieving greater success in teaching as evidenced by pupil achievement and the trainees' applications of learning principles. In a related experiment, McNeil added to these findings by demonstrating that student teachers effected superior student growth when their own grades depended on the appropriateness of the goals they selected for their students and on their students' mastery of those goals. Additional studies through the years have corroborated McNeil's early work, indicating that teaching with specific goals that focus on student outcomes increases teacher success and student achievement.

GUIDING LEARNERS
Industrial and social psychology studies of individual and group goals suggest that an individual functions better when clear about expected goals. Learning theory also supports the importance of students being aware of the goals toward which they strive. Such understanding theoretically helps learners recognize errors and improve performance, and this power to discriminate among responses affects the attainment of skills. In addition, a substantial number of studies documents that student knowledge of goals enhances learning.

STRUCTURING EVALUATION
As was already discussed, a primary impetus for the use of goals in education has been to structure the evaluation, or accountability, process. Once a well-formulated goal has been specified, it structures the methods for assessment and evaluation.

BASIC CONSIDERATIONS: BACKGROUND FOR SCHOOL PSYCHOLOGISTS

With changing demographics in the school-age population, school reform efforts that focus more on collaboration among professionals, and inclusion of students with disabilities within general education classrooms, the need for solving individual student problems should increase and the roles that school psychologists serve in the schools should continue to become more varied. Consequently, the need for school psychologists to assume the role of problem solvers and to adopt a problem-solving approach to their professional activities should grow.

The concept of a problem-solving approach, as presented in this volume, is characterized by defining problem behaviors in behaviorally specific and discrete form, assessing those behaviors by using low inference methods, setting goals in relation to baseline levels, formulating interventions to ameliorate problem behaviors, direct and frequent monitoring to gauge progress, and terminating services when goals have been realized. Central to guiding a successful problem-solving approach, consequently, is the definition of the problem and specification of the goal: With a well-specified goal, the evaluation and assessment process is structured, the teaching and intervention process is directed, and learners are guided toward problem solution. In school settings where a problem-solving approach is central to the innovation process, school psychologists need to be prepared to assist fellow professionals in developing important and useful goal statements. To be prepared, school psychologists must be grounded in the principles that guide useful goal statements.

Principles for Useful Goal Statements

In this section, basic considerations are reviewed for writing useful goal statements. Through the information presented, the argument is that effective goals must be student centered, clear and precise, ambitious, focused on long-term outcomes, descriptions of generalizable behavior within authentic settings, and developed through a collaborative process.

STUDENT-CENTERED VERSUS TEACHER-CENTERED
In useful goal statements, the verb does not describe teacher activities (e.g., the teacher will teach early civilization). Such statements of teachers' plans are helpful only after we have determined what we want students to accomplish. Consequently, outcomes that describe what we want students to accomplish should be the focus for direction and evaluation of instruction and, correspondingly, for our goal statements.

The relationship between teacher- and student-centered goals is analogous to the relationship between learning processes and learning products. For Teacher A, the learning process might include having students trace letters in the air and complete Frostig worksheets; for Teacher B, the learning process might include providing phonics instruction and lots of opportunity for students to read literature. In both cases, however, the learning product, or goal, is identical: reading first-grade text proficiently.

As this example illustrates, goals should not provide outlines of the instructional methods or describe the content to be covered in a curriculum. When goals do focus on instructional methods or content coverage, those goals are met when the instruction has been provided or the content has been presented, regardless of whether students have changed in any intended way. Unfortunately, in many school districts today, a strong emphasis on content coverage exists, pressing teachers to cover material in lockstep fashion, regardless of whether students are learning the presented material. In contrast to such a focus on content coverage, goals should focus on student mastery.

CLEAR AND PRECISE

Research (e.g., Melton, 1978) indicates that the more clear goals are, the more likely participants are to attempt to meet them. This finding corroborates learning and measurement theory indicating that clear goals provide more useful information both to learners for discriminating correct performances and to professionals for structuring instruction and evaluation.

AMBITIOUS

If we accept the premise that goals are important in directing human behavior, then the ambitiousness of the goal must be critical in determining how functional the goal will be. If goals are too easy to attain, then they fail to sustain meaningful behavior. If, on the other hand, they are exceedingly difficult to achieve, then they may serve to discourage functional behavior.

Within educational settings, unambitious goals, which are relatively easy to achieve, may allow educators to appear more successful than they really are. By contrast, appropriately ambitious goals, which may reduce the appearance of success in the short run, may intensify programs and serve to enhance outcomes in the long run.

In investigating the issue of goal ambitiousness, Fuchs, Fuchs, and Deno (1985) explored the relation between student achievement and goal ambitiousness and goal mastery. Participants were 58 special education students for whom teachers assessed baseline performance and set reading goals employing a standard format. On the basis of the relation between baseline and the stated goal, students were assigned to highly ambitious, moderately ambitious, and low goal groups. For 18 weeks, teachers worked to achieve their goals. At the beginning and again at the end of the study, student achievement was measured; at the end, goal mastery was determined. Analyses revealed that the ambitiousness of the goals was associated positively with achievement. Goal mastery, however, was not. That is, teachers who geared their efforts toward more ambitious goals effected better achievement outcomes, regardless of whether or not students actually met their goals.

In a related study, Fuchs, Fuchs, and Hamlett (1989) contrasted two decision-making structures used in conjunction with an ongoing assessment system; that is, Curriculum-Based Measurement (CBM). Ten teachers participated in a contrast group, in which CBM was not used. Ten teachers participated in a conventional CBM treatment in which, once the goal was specified at the beginning of the year, teachers were free to increase their goal at any time; and the formal decision rules, however, never required them to increase the goal. The final group of 10 teachers participated in a CBM treatment in which the decision rules prompted an increase in the goal whenever the student's performance indicated that the student might be able to surpass the initially specified goal.

At the end of a 15-week treatment period, results indicated that teachers in the goal-raising treatment actually did increase goals more frequently than the conventional CBM treatment teachers. Moreover, as might be expected, the goals of the goal-raising teachers were more ambitious than the conventional CBM treatment teachers by the end of the study. Most importantly, however, the achievement of the students in the goal-raising treatment surpassed that of the contrast group, whereas the achievement of the conventional CBM treatment group did not.

Consequently, it appears important for practitioners to specify ambitious goal statements. Unfortunately, guidelines for determining ambitious goals for individual students are difficult to identify. In sections to follow, I review some specific methods for monitoring goals and ensuring appropriate goal ambitiousness.

LONG TERM VERSUS SHORT TERM

A basic distinction between classes of goal statements is whether they focus on what the student will accomplish in a short time frame (i.e., within the next week or month) or whether they focus on what the student will accomplish in a longer time frame (i.e., by the end of the year).

With a short-term goal approach, the teacher specifies a hierarchical curriculum, representing the sequence of skills to be mastered during the year. Each skill in this hierarchy then becomes the target of one short-term goal. For example, if the teacher planned for the student to master phoneme-grapheme associations at the beginning of the year, then the teacher would specify a goal indicating mastery of phoneme-grapheme associations, and would focus on this goal until mastery was demonstrated. Then, the teacher would refocus on the next goal in the hierarchy: perhaps reading consonant-vowel-consonant words. In this way, throughout the year, the teacher would periodically shift goal statements, as skills in the hierarchy were sequentially mastered.

By contrast, with a long-term goal approach, an annual goal is specified, and a large pool of related measurement items is created. For example, if the long-term goal were for the student to read third-grade text proficiently, a large pool of reading passages representing third-grade text would be prepared, from which passages could be drawn for frequent measurement of the student's reading proficiency. Regardless of the teacher's current instructional methods, the goal statement (and its related measurement strategy) would remain constant.

Short- and long-term goal approaches differ conceptually and practically (see Fuchs and Deno, 1991, for discussion). With a short-term goal approach, the goal focuses on the current instructional material and makes goal attainment relatively easy to realize. Because of those dimensions, short-term goals are relatively sensitive to the effects of instructional programs and, therefore, can be satisfying for teachers and students.

Distinct disadvantages, however, also apply to a short-term goal approach. First, because the goal structure requires mastery of one goal before instruction on the next goal can begin, the validity of this hierarchy for an individual child is critical. Unfortunately, the hierarchy specified with a short-term goal approach almost always is hypothetically rather than empirically determined and, therefore, often of questionable relevance for an individual child. Second, because a short-term goal approach focuses on one skill at a time, it does not address cumulative mastery and coordinated use of multiple skills. Consequently, it is not unusual, especially for students with learning difficulties, for teachers to find that, although students have mastered single skills sequentially through the year, those students have failed to demonstrate the capacity at the end of the year to utilize the multiple skills in an integrated fashion. Such a failure may explain the documented, relatively poor relation between number of skills mastered during the year and performance on end-of-year global achievement tests. Essentially, although it takes longer to see student improvement with a long-term goal approach, long-term goals better represent the ultimate desired outcome that we want to see students demonstrate.

At a practical level, a long-term goal approach offers additional advantages because, typically, only one goal statement is needed to describe the outcome we expect within a given domain. This translates into one elegant system for monitoring the student's acquisition of desired outcomes. By contrast, with a short-term goal approach, many different goal statements are required; and, for each statement, a different system for monitoring mastery is required. This can lead to a complicated, unmanageable system. For example, Safer and Hobbs (1979) reported that nearly one-quarter of the IEPs they examined were at least 11 pages long, with goal statements comprising most of the documents. These goals covered small details that essentially outlined the components of the instructional programs the students were to receive. Numerous, specific goals render the task of monitoring progress cumbersome: With an excessive number of goals to track, teachers are faced with the overwhelming task of designing and administering measurement procedures for multiple goals, a situation that often leads to infrequent compliance with the IEP monitoring requirement (Thurlow & Ysseldyke, 1979). A long-term goal approach can streamline the process of monitoring goal attainment and, thereby, enhance compliance.

DESCRIBE GENERALIZABLE BEHAVIOR WITHIN AUTHENTIC SETTINGS

Related to a focus on long- rather than short-term goals is the notion that, to the greatest extent possible, goals should describe generalizable behavior within authentic settings. To illustrate this principle, consider the following proposition: Goals that focus on reading connected text represent more generalizable behaviors and are more applicable to real-world tasks than are goals that focus on reading lists of *r*-controlled words. In a similar way, goals that focus on spelling words correctly within naturally written compositions represent more generalizable behaviors and are more applicable to real-world tasks than are goals that focus on spelling lists of dictated words.

The extent to which we can focus our goals on the real-world outcomes we desire of students, the more those goals are authentic and the greater the probability that the instruction teachers provide and the evaluation methods they employ will result in students' acquisition of important, global skills for successful life adjustments. Consequently, goals should be statements about broad skills within even broader domains. They structure what broad skills a child will attain in a relatively long time frame. What follows are relevant questions for practitioners to ask as they consider alternative goals: Is this outcome necessary for students to function ultimately in complex heterogeneous community settings? Could students function as successful, employed adults if they did not accomplish this outcome? Do other, more important outcomes exist relating to overall academic or social competence?

DEVELOPED THROUGH A COLLABORATIVE PROCESS

Useful goals tend to be formulated through a collaborative process in which multiple perspectives about what constitutes critical outcomes for an individual child are consulted. Relevant participants include current teachers across different subjects or settings, future teachers who will receive students at higher grades or in less restrictive settings, parents, community representatives including potential employers, coaches, and church leaders, as well as current and former students. School psychologists, because of their frequent training in collaboration and consultation, can be the ideal professionals for coordinating such a collaborative process for formulating goals.

BEST PRACTICES

In this section, three practices for identifying and monitoring the attainment of critical outcomes are discussed: goal attainment scaling, curriculum-based measurement, and a standard core of outcomes. In addition, once the critical outcome has been identified, a level of desired performance typically must be specified. Therefore, this section concludes with a review of three strategies for selecting performance levels: referencing goals to inter-individual norms, employing intra-individual norms, and comparing an individual's own performance over time.

Practices for Identifying and Monitoring the Attainment of Critical Outcomes

GOAL ATTAINMENT SCALING

Goal Attainment Scaling (GAS) (Carr, 1979; Lenz, Ehren, & Smiley, 1991) involves establishing goals and specifying a range of outcomes that would indicate progress toward achieving those goals. GAS comprises four essential steps. First, the teacher, student, parents, and principal decide mutually on general goals such as "improved personal grooming" or "reduced errors in number facts." Second, each participant assigns a weight or number value to each general goal so that the summed weight across all the general goals equals 100. Third, the teacher breaks down each goal into a set of concrete behaviors. These behaviors represent a continuum of alternative behavioral outcomes ranging from most to least desirable within each general goal; a description of the likelihood that the behavioral statement will be achieved is attached. Finally, a student's functioning at any given time is described numerically: Within a goal, the best-fitting behavioral statement (with its corresponding numerical value) is identified; across goals, the products are summed.

In terms of the principles specified earlier in this paper, GAS satisfies some criteria for useful goals more than others. Its strengths include a focus on student outcomes rather than on teacher outcomes; its clarity and precision; its potential for encouraging ambitious outcomes; and its deliberate emphasis on a collaborative process for formulating outcomes. Depending on how GAS is implemented, however, it does not necessarily satisfy the criterion for a long-term approach to goal setting, and it may fail to meet the critical condition that the goal behavior focus on generalizable behavior necessary in authentic settings. Nevertheless, if practitioners employ GAS with a conscientious attempt to focus participants on long-term outcomes that require generalizable behavior in authentic settings, then GAS can meet the multiple principles offered in this chapter for useful goals.

CURRICULUM-BASED MEASUREMENT

CBM (Deno, 1985; Fuchs & Fuchs, 1998) is a set of procedures for monitoring student progress. To monitor student progress, it is necessary to identify the goal toward which progress is referenced. Consequently, a major dimension of CBM methods is goal specification.

Within the CBM research program, questions pertaining to how to specify goals became subsumed under the larger question of "What to Measure" (see Deno & Fuchs, 1987). In studying what to measure, CBM developers specified alternative procedures for measuring a student's proficiency within a domain (e.g., in reading: answering questions about the content read versus reading a list of words aloud versus reading connected text aloud versus restoring missing words in text). Then the researchers investigated how well each procedure (a) related to other socially important measures of proficiency, (b) could be implemented accurately, (c) reflected student growth, (d) could be integrated for frequent measurement within the context of busy and complicated classroom settings, and (e) could be used by teachers to improve their instructional program and enhance student achievement.

In each content area (i.e., reading, spelling, written expression, and mathematics), one or two alternative formats for specifying annual outcomes satisfied the multiple criteria. For example, research (see Shinn, 1989, for synthesis) supported reading connected text aloud as a critical indicator of overall reading proficiency. Reading aloud from connected text (a) relates well to many other socially agreed upon indicators of reading proficiency, (b) is simple and straightforward so that it could be implemented accurately, (c) reflects student growth as it occurred, (d) can be integrated into busy classroom settings, and (e) can be used by teachers to improve their instructional programs and enhance student achievement.

This overall indicator of reading proficiency, reading connected text aloud, could be incorporated in end-of-year goal statements to represent the outcome teachers expect in the area of literacy. In applying the principles specified earlier in this chapter, reading connected text aloud meets the requirements for useful goal statements. It specifies what students, rather than teachers, will accomplish. It communicates clearly and precisely about expectations. It can be used to frame ambitious levels of desired performance. It focuses students and teachers on the long-term outcome that we expect at the end of the year. It requires that long-term outcome represents generalizable behavior, which requires integrated performances of multiple skills (e.g., reading words with different phonetic patterns, reading sight vocabulary, using comprehension to enhance fluency) and which is necessary in authentic settings. And it specifies the level of desired behavior or the text within which the performance will be expected can be specified through a collaborative process involving individuals with a variety of perspectives.

In addition, CBM provides an elegant system for monitoring students' goal attainment. Within an academic domain it requires practitioners to measure only one integrated system that simultaneously represents the multiple components of the teacher's curriculum and instructional program. Therefore, it can be used efficiently and feasibly.

STANDARD CORE OF OUTCOMES

The notion of a standard core of outcomes represents an extension of CBM. The basic idea (Deno, personal communication, 1993) is that, within any behavioral domain, the field can identify standard tasks that (a) represent overall indicators of proficiency, (b) can be used to specify the outcomes of schooling that are critical to successful life-long adjustments, and (c) can structure a measurement process whereby practitioners can efficiently monitor a student's standing and attainment of critical outcomes.

Although a comprehensive system of standard outcomes has yet to be developed, the initial work on CBM in the areas of reading, spelling, written expression, and mathematics provides a model for subsequent development of a system of standard outcomes. A key distinction between CBM and a comprehensive system of standard outcomes is that, unlike CBM, the goal statements within a comprehensive system of standard outcomes is not linked to the student's curriculum. An advantage of disconnecting the specification of goals or outcomes from the student's specific curriculum is that the disconnection allows all students to be described in reference to the same standard; and this facilitates comparisons across specific settings and contexts. See Fuchs and Deno (1991) for a discussion of the advantages and disadvantages of measuring students directly from their own curriculum.

In all other ways, however, a system of standard outcomes should enjoy the benefits of a system like CBM: The outcomes are student centered, are clear and precise, can encourage ambitious expectations, and focus on long-term goals and generalizable behavior in authentic settings. Moreover, such a system requires collaboration across parties representing multiple perspectives.

Practices for Selecting Levels of Performance for Goals

Once a basic framework for specifying a goal has been identified, the difficult task of selecting a level of desired performance remains. Consequently, if the school psychologist determines, in coordination with school staff, that a GAS framework will be adopted, then the school psychologist still needs to identify what levels of outcomes should be incorporated into, for example, the on-task goal statement (e.g., most unfavorable outcome: student is on task 10% of the time; less than expected outcome: student is on task 25% of the time; expected outcome: student is on task 50% of the time). If the school psychologist determines, in coordination with the school staff, that a CBM framework will be adopted, then the school psychologist still needs to identify what levels of outcomes should be incorporated into, for example, the reading goal statement (e.g., given third-grade passages from the Holt curriculum, the student will read 125 words correctly in 1 minute). In this next section, alternative strategies for identifying levels of performance for goal statements are reviewed.

REFERENCING TO INTER-INDIVIDUAL NORMS

As was illustrated in the early work of Deno and Mirkin (1977), one sensible strategy for selecting levels of performance for goals is to measure other, more proficient students' levels of performance in the relevant domain and to set the target student's goal so that the student will demonstrate performance commensurate with that of the more competent peers.

In the most simple, manageable version of inter-individual norm referencing for the specification of performance levels, a school psychologist may sample several students within a general education classroom at the appropriate grade level. Let's say, for example, that Charlie is a student with a learning disability, receiving reading instruction within the special education resource room. The special educator deems fourth-grade material as a reasonable level of difficulty within which the student may achieve competence by the end of the year, and the teacher specifies the goal as, "Given fourth-grade passages from the Holt series, Charlie will read X words correct within 1 minute." The teacher does not, however, have a concrete way of operationalizing "competence" for specification in the goal statement; that is, the teacher does not know how many words correct Charlie should read to denote proficiency. The school psychologist can assist the teacher by sampling three to five students from two different fourth-grade classrooms: having each student read fourth-grade passages for 1 minute, averaging the scores, and using this number to denote proficiency for Charlie.

This method has the advantage of being empirically based, even as it focuses the teacher on a level of proficiency that should facilitate the target student's re-entry into a less restrictive setting should the goal be achieved. Nevertheless, this method is also problematic because while Charlie is striving toward the empirically derived criterion of performance, his general education peers also are improving. Therefore, when Charlie achieves the specified goal, his general education peer will have surpassed Charlie's achievement.

At least partly because of this problem, some school systems have moved to establishing norms for their school district or schools, within their selected goal framework. Some districts that rely on CBM methods for goal specification, for example, have collected norms describing how many words per minute typical students in the districts' schools read aloud from grade-level material at the beginning, middle, and end of the academic year. With such norms routinely available, practitioners have a database that allows appropriate inter-individual goal levels to be specified at any time. Shinn, Tindal, and Stein (1988) describe methods for collecting local CBM norms.

REFERENCING TO INTRA-INDIVIDUAL NORMS

Inter-individual norms for setting goals are empirically defensible and allow special educators to set their expectations in terms of how students within general education perform; that is, facilitating sound decisions about when students with disabilities may be moved successfully across instructional settings. Unfortunately, this method of establishing performance criteria for goals does not take into consideration a student's beginning of the year performance:

All third graders may have year-end reading goals set at the normatively appropriate level of 125 words read correctly per minute (WCPM). However, for a student with a beginning rate of 75 WCPM, this goal would represent an expected weekly increase of 1.67 WCPM ([125 – 75]/30 weeks); for a student with an incoming rate of 25 WCPM, the expected weekly increase would be considerably larger ([125 – 25]/30 weeks = 3.33 WCPM). Consequently, relying on cross-sectional normative data can result in varying standards for weekly rates of growth.

One alternative method for specifying performance criteria for goals is to monitor intra-individual student progress over time and to calculate normative data directly from students' weekly rates of improvement. With such a method, students in a school district are to be monitored in terms of the number of words they read aloud from text each week. At the end of the year, the average weekly rate of improvement is derived for typical students at each grade level within a performance domain. Then, the weekly rate of improvement is used to specify the performance criterion.

For example, as illustrated by Fuchs, Fuchs, Hamlett, Walz, and Germann (1993), when measured each week in terms of the number of words read aloud from text in 1 minute, second-grade students typically increase 1.46 words each week. Consequently, if a goal were specified for a student to read second-grade text, a teacher could select a performance criterion that establishes a weekly rate of growth commensurate with what we would expect normally achieving second graders to demonstrate; i.e., approximately 1.50 words per week. So, if the student initially read 35 WCPM from second-grade text, the performance criterion might be 80 WCPM ([1.5 x 30 weeks] + 35). Although this outcome may not place the student at a level commensurate with normally achieving second graders at year's end, it would denote a rate of progress commensurate with normally achieving second graders.

INTER-INDIVIDUAL COMPARISONS OVER TIME

A third option for specifying the performance criterion also involves empirical determination. In contrast to an inter-individual or an intra-individual normative approach, however, this third option does not rely on other children to derive the empirical determination. Rather, it relies on the student's own rate of improvement to formulate the end-of-year goal in a data-based dynamic (i.e., ever-changing) way.

As was illustrated by Fuchs et al. (1989), after a teacher relies on professional judgment to specify an initial performance criterion, the teacher continuously monitors the student's progress. When the student's rate of progress matches or exceeds the rate of improvement specified in the initial goal, the teacher increases the end-of-year goal, in an attempt to maintain ambitious goals, relative to what the student is demonstrating he/she can achieve.

For example, let us say that the student's baseline performance was 35 WCPM in fourth-grade text and that the teacher's best judgment was that for the end of year goal (30 weeks away) the student would read 70 WCPM in fourth-grade text (i.e., a weekly rate of improvement of 1.16 words ([70 – 35]/30 weeks). After 6 weeks of implementing the teacher's instructional program, she finds that the student is increasing the weekly score by 1.6 words. At that time, the end-of-year would be reset to 83 (after 6 weeks, the student's current performance level is 44.6; that is, [1.6 x 6 weeks] + 35 baseline; for the next 24 weeks, she will now expect a continued weekly increase of 1.6: [1.6 x 24 weeks] + 44.6 = 83). The teacher continues to monitor the student's performance each week. In this way, whenever the student's weekly rate of improvement increases, the goal is reset accordingly always using the student's own best performance to determine an appropriately ambitious performance criterion for that individual student.

SUMMARY

The focus of this chapter was specifying student goals and outcomes. After the topic was defined and the history, rationale, and current context were explored, three purposes for focusing attention on goals and outcomes were specified: directing teaching and curriculum development, guiding learners, and structuring evaluation. Then, applications for school psychologists were reviewed and basic considerations for writing useful goals statements were described. These basic considerations indicate that goals should be student centered, clear and precise, ambitious, focused on long-term outcomes, descriptions of generalizable behavior useful within authentic settings, and developed through a collaborative process. With those considerations as background, three alternative frameworks for specifying goals were described, Goal Attainment Scaling, curriculum-based measurement, and a standard core of outcomes. Finally, three empirical strategies for specifying performance criteria were discussed: inter-individual norms, intra-individual norms, and referencing to an individual's own ongoing performance.

ANNOTATED BIBLIOGRAPHY

Carr, R. A. (1979). Goal attainment scaling as a useful tool for evaluating progress in special education. *Exceptional Children, 46*, 88–95.

This article provides a rationale and specific guidelines for implementing Goal Attainment Scaling. Examples of specific scales applicable to special education are presented and methods for scoring are illustrated.

Fuchs, L. S., Fuchs, D., Hamlett, C. L., Walz, L., & Germann, G. (1993). Formative evaluation of academic progress: How much growth can we expect? *School Psychology Review, 22*, 27–48.

This article provides an overview of alternative methods for formulating performance criteria within goal statements. A methodology for collecting intra-individual normative data is outlined; intra-individual norms for curriculum-based measurement in the areas of reading, spelling, and math are provided.

Shinn, M. R., Tindal, G., & Stein, S. (1988). Curriculum-Based Measurement and the identification of mildly handicapped students: A research review. *Professional School Psychology, 3*, 69–86.

This synthesis specifies a methodology for collecting inter-individual normative data for CBM and reviews previous studies investigating the utility of such a framework for identifying students for special education services.

38 Best Practices in Collaborative Problem Solving for Intervention Design

Sarah J. Allen and Janet L. Graden
University of Cincinnati

OVERVIEW

This chapter describes a process, collaborative problem solving, that can guide decision making and intervention planning for improving academic and behavior outcomes for students. The primary focus is on the two basic components of the term collaborative problem solving. *Collaborative* refers to the working relationship between the participants in problem solving—the teacher(s), parent(s), student, and school psychologist and/or other school personnel—who are *active, meaningfully involved participants* in all phases of planning and decision making. *Problem solving* refers to the *systematic approach* used to conceptualize a problem situation and identify needs, analyze factors contributing to the problem situation, design strategies to meet those needs, and implement and evaluate the strategies. Collaborative problem solving, with a foundation in consultation as a service delivery approach, is an effective and efficient way of providing services because it aims to help more students, focus on solving problems in direct ways, involve relevant individuals in the intervention planning, and ultimately enhance classroom and school success for students.

Collaborative problem solving as a model for organizing service delivery not only is well supported in the literature (e.g., Gutkin & Curtis, 1999; Idol, Paolucci-Whitcomb, & Nevin, 1994; Pugach & Johnson, 1995), but is consistent with directions in federal law and educational initiatives focusing on improving student outcomes. For example, the Individuals with Disabilities Education Act 1997 (IDEA 97) includes strong emphases on collaboration of key participants (e.g., parents, general education teachers) in all aspects of decision making, including "pre-referral" activities, and on linking assessment directly to intervention planning. School reform efforts nationwide emphasize increased performance standards and increased accountability, highlighting the need to use problem solving at all levels (individual student, targeted group, school-wide) to implement high quality intervention approaches to improve student learning and behavior outcomes. Educators and parents, in both general and special education, desire effective approaches for instruction and behavior to meet the needs of improving outcomes for *all* students (Roach, 1992).

As a method for systematically approaching assessment and intervention design, collaborative problem solving also represents a useful way for school psychologists to conceptualize and organize service delivery. By using a systematic approach to collaborate with others to clearly identify concerns, analyze and evaluate the factors affecting the concern, design and implement strategies to remediate or eliminate the problem situation, and evaluate specific intervention outcomes, problem solving provides an underlying framework for addressing the many different problems and needs of schools today. For example, collaborative problem solving can serve as a process to systematically address class-wide or system-wide intervention design (e.g., addressing school-wide positive behavior support, effective academic strategies, crisis intervention planning).

In a time when students are experiencing significant learning and emotional challenges and schools are struggling to meet diverse needs with sometimes fewer resources, school psychologists can be vital team members to address these issues. In many instances, this will require a shift from primarily diagnostic roles related to special education eligibility to the role of problem-solving facilitator and participant. The national context is conducive to such a shift in role and activities, as special education law specifically includes emphases on collaboration and linking assessment to intervention planning; similarly the National Association of School Psychologists' *Blueprint for Training and Practice* highlights the centrality of data-based problem solving across activities (Ysseldyke et al., 1997).

FOUNDATIONS FOR PROBLEM SOLVING

Collaborative problem solving as a framework for approaching problem situations has its foundations in many interrelated literatures in school psychology, psychology, education, and special education. Among its key foundations are a scientist-practitioner approach; ecological and behavioral approaches to conceptualizing problems, assessing, and intervening; and consultation.

Scientist-Practitioner Approach

In a scientist-practitioner approach to services delivery (described in Barlow, Hayes, & Nelson, 1984), the practitioner relies on research to guide assessment and intervention decisions, and intervention choices are treated as testable hypotheses. In this framework, all assessment is linked *directly* to intervention—assessment serves the purpose of gathering information to answer specific questions to inform intervention choices. Interventions are selected to reflect the most supportable hypotheses and the best predictions regarding potential for success, based on prior research or founded in theoretical conceptions. Another important feature is that interventions, as testable hypotheses, must be systematically monitored to assess whether they produce desired outcomes. Thus, informed decision making, question-focused assessment, a rationale for intervention selection, and a reliance on systematic data collection to monitor intervention outcomes are central features of a problem-solving approach to intervention premised on a scientist-practitioner model.

Behavioral and Ecological Foundations

Although a generic problem-solving approach for addressing child-related problems is not linked solely to behavioral and ecological foundations, eco-behavioral approaches to assessment and intervention planning provide a strong, direct framework for problem solving (Gutkin, 1993). Eco-behavioral approaches stress the importance of:

1. Specifically defining and clarifying concerns

2. Analyzing contexts in which behaviors occur and variables that are hypothesized to affect, control, and reinforce the behavior

3. *Directly* (versus indirectly) assessing the behavior(s) of concern in relevant environments

4. Intervening directly and in relevant environments

5. Directly assessing intervention outcomes

This eco-behavioral approach to problem solving and intervention design can be contrasted with, for example, a diagnostic-prescriptive approach focused on assessing to determine a diagnostic label or category (e.g., learning disability, attention deficit disorder) that leads to general intervention recommendations presumed to be related to the category/label. In contrast, an eco-behavioral approach focuses on *specific* behaviors, skills, deficits, excesses, and environmental supports needed to enhance skills and support desired behaviors and performance. Obviously, eco-behavioral approaches include an examination of the *context* in which behavior or learning occurs. Thus, an ecological approach moves away from a primary emphasis on a conception of a problem as child focused and toward an understanding of a behavior or situation in its context. Major features of an eco-behavioral approach are described in more detail in Conoley and Haynes (1992), Gutkin (1993), and Knutson and Shinn (1991).

Consultation

Consultation has long been promoted as a way to organize service delivery and to assist teachers and parents to develop interventions for children. The consultation literature includes descriptions of several consultation models (e.g., behavioral consultation: Bergan & Kratochwill (1990); mental health consultation: Caplan & Caplan (1999); collaborative consultation: Conoley & Conoley (1992), Idol & West (1987); collaborative eco-behavioral problem-solving–based consultation: Gutkin & Curtis (1999)). However, to a large extent, as described in major consultation texts (e.g., Brown, Pryzwansky, & Schulte, 2000), these various approaches for organizing and describing consultation share some common characteristics. All emphasize, to some extent, relationship building and interpersonal variables, including developing a collaborative relationship. All also use a systematic approach to problem solving that involves the basic steps of problem identification, analysis of relevant features affecting the problem situation, intervention planning and development, and evaluation of progress toward desired outcomes.

Although the consultation literature was used heavily for the framework for this chapter, we have come to prefer the term *collaborative problem solving* to consultation for school practice, because the term:

1. Is more descriptive of what actually occurs in the consultative process
2. Emphasizes the collaborative nature of the problem solving across all phases
3. Avoids some terms used in the consultation literature (e.g., consultant, consultee) that by their very nature seem to imply an expert/recipient model, with the consultant being the expert and the teacher or parent being the more passive recipient of the process

In collaborative problem solving as described here, all participants engage actively in all phases of the process, in differing yet vital roles that are discussed in more detail in the following section on collaboration and throughout the description of problem-solving steps.

ASSUMPTIONS UNDERLYING PROBLEM-SOLVING APPROACH

Careful consideration of the features of a collaborative problem-solving approach to intervention design reveals some key operating assumptions that underlie this approach, both in theory and in practice. Understanding and adopting these assumptions are essential to effective implementation of the approach.

All Children Can and Will Learn

Asserted as a guiding principle of the National Association of School Psychologists' review of policy and practices regarding assessment and eligibility in special education is the premise that "all children can learn" (National Association of School Psychologists, 1994, p. 2). Some children learn faster or slower, and some learn best differently than others. However, an important belief is *all* children have the potential to learn. Further, federal legislation dictates that all children have a right to a free and appropriate education regardless of categorical label. As a result, it is incumbent upon education systems and school professionals to deliver services that are *responsive* to the needs of all children—with and without disabilities or any other education or behavior support need.

The primary implication of this assumption for a problem-solving approach is that it becomes the *task of problem solving* and the *responsibility of the problem solvers* to discover the right *conditions* (e.g., instructional strategies, supports) that will enable children to learn. In this view, identification of a deficit or a need is only the first step in problem solving, not a goal in itself. Relatedly, by emphasizing conditions for learning, the focus is not only on child skills and needs but on environmental *supports* required to meet those needs. Thus, problem-solving steps aim to promote understanding of behavior and learning in context and focus on *what can be changed* (i.e., interventions) to improve child outcomes.

Collaboration as a Foundation

Collaboration, meaning the working relationships among participants in problem solving, provides the means for implementing a problem-solving approach in schools. Participants typically include the classroom teacher(s) responsible for the student, parent(s) of the student (the term parent refers to any family member or guardian responsible for the child), and school psychologist and other school personnel. The concept of collaboration is well founded across many literatures (e.g., Dunst, Trivette, & Deal, 1988; Friend

& Cook, 2000; Gutkin & Curtis, 1999; Pugach & Johnson, 1995) and has been the topic of definitional discussion in the school psychology literature (e.g., Erchul, 1999; Gutkin, 1999a, 1999b). In use here, collaboration refers to the nature of the working relationship between participants. Collaboration begins with assumption that all stakeholders are *valued participants*, with differing but equally important contributions, roles, tasks, and expertise. Importantly, in a collaborative process, there is no one "expert"; all participants are seen as having expertise and important contributions. This definition is consistent with the emphasis on collaboration pervading IDEA 97, in which parents and general education teachers are highlighted as key participants in all aspects of planning and decision making.

The collaborative relationship in problem solving is operationally defined by specifying the nature of the relationships (e.g., willingness to participate, shared responsibility for problem resolution and for completion of tasks), roles (e.g., contributions to the problem-solving process), and the methods of interacting and communicating (e.g., shared understanding of the decision making process to be used, mutual goals, clear roles, and responsibilities). In our approach to collaborative problem solving, all participants are actively and meaningfully involved in *all steps* and decisions, and the process itself (problem solving) is made overt so that all participants can understand and contribute to decisions. How collaboration comes in to play at each step is highlighted in the discussion of the problem-solving steps.

Problem *Solving*, not Problem Finding, Sorting, Labeling, or Admiring

All too often the process of trying to help children with academic or behavioral needs gets stalled at the point of describing what is wrong with the current situation, or "admiring the problem," rather than refocusing efforts on what can be done to improve the situation. Considerable time and energy of all participants (teachers, parents, school psychologists) often is devoted to assessing and diagnosing a problem for the purpose of a determining a categorical label. When the focus is shifted to problem *solving*, very specific steps are used to identify and provide the support, strategies, services, and/or accommodations needed to resolve the current problem situation, and an emphasis is placed on finding solutions (strategies) instead of staying focused on problems. Implicit within this problem-solving assumption is that all assessment or data gathering activities must be *directly* linked to intervention planning (consistent with IDEA 97). Thus, assessment becomes very focused, individualized to the situation, and intervention-driven, in contrast with a typical "assessment battery" approach. Problem solving seeks to design situation-specific strategies for situation-specific needs.

IMPLEMENTING COLLABORATIVE PROBLEM SOLVING

System-Wide Support for Implementation

Although a detailed discussion is beyond the scope of this chapter, it is important to recognize the critical need to establish system-level conditions and support for implementation of collaborative problem solving. Both use of the process and implementation of interventions are influenced by system-level variables such as policies, services delivery, and training that provide the conditions for collaborative problem solving at the school or district level (Rosenfield & Gravois, 1996). System-wide implementation of collaborative problem solving can be maintained only when there are sufficient resources and incentives for staff to effectively engage in the problem-solving process and implement intervention plans, and critical among these is time for collaboration. Collaborative problem solving is more effective when used consistently as the basis by which a school or district addresses the needs of students, rather than in isolated situations or by only some staff.

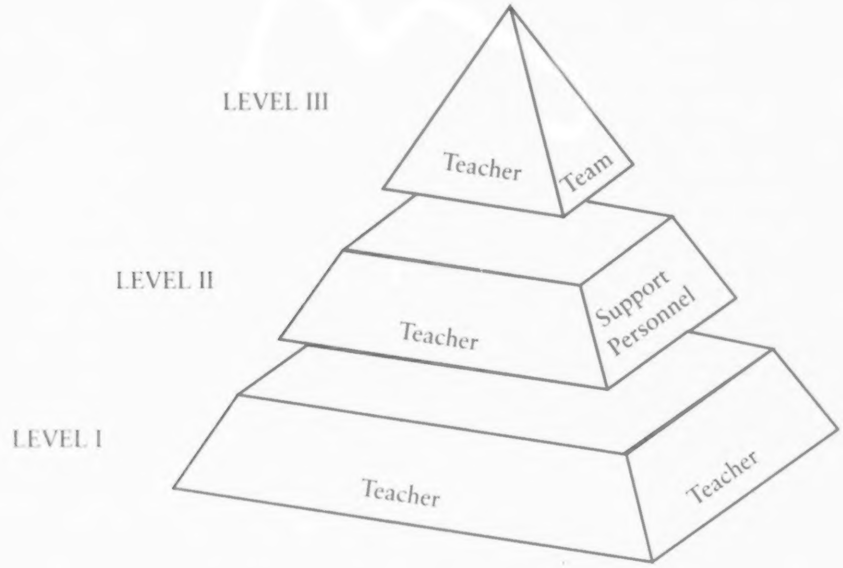
Multi-Level Service Delivery System

Reflecting the need for and availability of support, efforts to intervene with student-related problem situations can occur at different levels within a school. Curtis, Curtis,and Graden (1988) provided a framework for conceptualizing implementation of the collaborative problem-solving process within a multi-level approach for intervention assistance resembling a pyramid (see Figure 1).

PERSONAL PROBLEM SOLVING

"Personal" problem solving refers to the point at which teachers, without seeking help of other collab-

Figure 1. Collaborative problem solving as a multi-level service delivery system



LEVEL III	Group Problem Solving
LEVEL II	Individual Consultation
LEVEL I	Personal Problem Solving

Note. From Curtis, M. J., Curtis, V. A., & Graden, J. L. (1988). Prevention and early intervention through intervention assistance programs. *School Psychology International*, 9, 257–264. Copyright 1988 by Sage. Reprinted by permission.

orators, attempt to intervene with student-related problem situations through their own problem-solving efforts. Teachers might modify instructional practices based on their own knowledge and expertise, and may discuss concerns and involve parents (and students, as appropriate) in their effort to address student needs by making changes within the classroom and/or at home. Beyond this, teachers may engage in informal problem solving with a colleague. In recognition of this fact, the first level of service delivery depicted on the pyramid involves classroom teachers collaborating in problem solving with other teacher(s). At this level, problem-solving steps and activities (e.g., delineating plans, monitoring changes) tend to naturally evolve from teachers' knowledge of strategies and the process is more informal and less intrusive. Ideally, when all levels of intervention assistance are fully implemented, this level is supported through teacher training in problem solving and providing time for collaboration.

ONE-TO-ONE PROBLEM SOLVING

At the next level of intervention assistance, classroom teachers and parents (with student input and/or participation) engage in collaborative problem solving through one-to-one consultation with education support personnel (e.g., school psychologist, speech pathologist, reading teacher, counselor) based on the knowledge and expertise each can contribute to addressing a problem situation. By using a more systematic approach, participants adhere to a more structured problem-solving process. Additionally, documentation of the process followed is more carefully recorded as evidence of decisions made and outcomes obtained. For example, Curtis et al. (1988) recommended that specific intervention plans be recorded and outcome data be monitored.

GROUP PROBLEM SOLVING

Within this multi-level intervention assistance system, the highest level is represented by team-based problem solving. The composition and function of the team should vary based on the specific expertise needed for the situation. There are various approaches for implementing this team-based model for collaboration described in more detail in Rosenfield and Gravois (1996), Shrag and Henderson (1996), and Zins, Curtis, Graden, and Ponti (1988). Certainly group problem solving is the most costly configuration of these service delivery options in terms of personnel time and resources and, therefore, is best used only to address the most complex and difficult situations. Readers are referred to other chapters in this book for discussion of operating pre-referral or intervention assistance teams.

BEST PRACTICES/ PROBLEM-SOLVING STEPS

Although the literature includes descriptions of many different models of problem solving, all use the same basic phases. For the purposes of this discussion the four-step model of problem solving outlined by Bergan (1977) and Bergan and Kratochwill (1990) will be used, including problem identification, problem analysis, plan development and implementation, and plan evaluation. Also, to at least some extent, all approaches to consultative problem solving emphasize the importance of developing a collaborative relationship among participants. We believe it is vitally important to collaborate meaningfully with teachers, parents, and students in problem solving, so we will highlight the importance of collaboration both in terms of establishing a relationship prior to beginning the process and the nature of the working relationship among participants at each step in problem solving.

The following discussion is intended to provide a clear understanding of the sequence and type of decisions problem solvers must make when presented with a student who is not meeting expectations. The *decisions* that need to be made are the same for students experiencing academic or behavioral problems, with and without disabilities. For each step in the problem-solving process, we highlight the *questions* to be answered, the *tasks* to be completed in order to answer these questions, some *methods* for accomplishing the tasks, the *outcomes* of the step, and some of the *common pitfalls* that occur. Links between assessment and intervention are delineated as the implications of decisions made at each step of problem solving are used to inform the subsequent steps. That is, the design, implementation, and evaluation of interventions aimed at resolving problem situations are determined from a clear understanding of the problem situation and factors related to its occurrence.

Establishing a Collaborative Relationship: How Will We Work Together?

Although not formally recognized within systematic problem solving, "Step 0" refers to the step *before* the first step of problem solving (T. B. Gutkin, personal communication, September, 18, 2000), or the work of establishing the collaborative relationship among participants that will provide the foundation for the following steps. The primary *question* to be addressed at this step of problem solving is, *How will we work together?* Specifically, what will be the nature of the working relationship among participants?

Both prerequisite for and underlying all remaining steps in the process, Step 0 involves the following *tasks*: establishing and maintaining rapport among participants, formulating a sense of trust and respect among participants, and clarifying expectations for participation, including roles and responsibilities of problem solvers, shared accountability, legal and ethical guidelines, preferred means of communication, and so forth. Additionally, it is helpful to establish among participants a shared understanding of the problem-solving process that will be used to guide decision making, including the objective, tasks, and outcomes of each problem-solving step.

Methods used at this step of problem solving are grounded in effective communication and basic helping skills (e.g., active listening, empathy, paraphrasing), but largely depend upon the circumstances under which problem solving is initiated. For example, the approaches used to address a highly emotional situation may differ from those employed when a calm and rational mind-set prevails among participants. Additionally, the strategies used to build rapport and establish clear communication differ among participants who have worked together previously and those working together for the first time.

Both prior to beginning and throughout problem solving, overt references to the problem-solving process can facilitate participants' understanding of decision making and enhance outcomes. For example, Cleven and Gutkin (1988) found that consultation interactions with cognitive modeling resulted in improved participant understanding of and ability to use problem-solving processes to address concerns regarding individual students. They suggested helping collaborators develop problem-solving skills by providing participants a cognitive road map of the problem-solving process to make the process overt.

The *outcome* of Step 0 is the establishment of a strong relationship among participants that supports ongoing collaborative problem solving efforts. Before proceeding, several necessary conditions for collaboration should be evident, including a sense of mutual trust and respect for other participants, a willingness to commit time and energy to the process being initiated, and some shared understanding of the work to follow. Last, a calm, rational composure must prevail among participants such that they are ready to move beyond "problem admiration" and undertake the work of problem *solving*.

Common pitfalls associated with Step 0 result from a tendency to rush certain steps or decisions. That is, participants sometimes seek solutions by either grabbing onto the first solution that comes to mind or offering suggestions and advice prematurely. Someone may assume or be assigned the role of "the expert" to which the others look for answers. Furthermore, sometimes the problem-solving process remains stalled as participants spend undue amounts of time and energy "admiring" the problem and/or identifying barriers to addressing it. Finally, a common pitfall of Step 0 is that participants begin their work without a clear or shared understanding of the goals, the roles and responsibilities of participants (including their own), or the collaborative problem-solving process itself. If the important work of Step 0 is not completed adequately, the hard work of problem solving that follows is likely to become much more difficult.

Problem Identification: What is the Problem?

The objective of the first phase of problem solving is specific problem identification to define and clarify concerns and targets for change. Premised on the assumption that the problem is situation-centered within an educational environment, the intent of this initial phase of problem solving is to clearly identify the discrepancy between expected and actual performance in a particular setting. Specifically, the problem is defined based on the mismatch between what is expected of the student to be successful in the environment and the student's current level of performance.

Questions to be answered at this phase include: *What is the problem?* Specifically, what does the student do (or not do) that has caused someone to perceive a problem? In defining and clarifying the problem to systematically include environmental factors, the question is broadened to: *What is the problem situation?* For example, a student does not complete assigned written work during independent work time, or a student hits other children when she does not receive an item requested. Rather than identifying problems in general terms such as a student is "unmotivated" or "learning disabled," it is necessary to ask what the student does (or does not do) specifically that are *indicators* of the more general concern. For example, an indicator of "unmotivated" may be an extremely low level of work completion, and an indicator of a learning problem may be poor reading fluency.

To specifically identify the concern, a number of *tasks* need to be accomplished during this phase of problem solving. Conceptualized as a funnel, the problem-identification process should begin from a broad base to identify all concerns, assets, and other related factors regarding a problem situation. First, problems may be described in general, global terms. As the funnel narrows, however, the problem(s) being identified also must be defined and clarified in more specific terms. For example, because problem situations often are complex in nature, it may be necessary to break the problem into component parts and to prioritize or logically group them either in terms of importance (e.g., most critical based on immediate needs), constellation or class of behavior (e.g., combining hitting, kicking, and breaking objects into a category of "destructive behavior"), or sequence (e.g., short term versus long term or prerequisite versus required skills).

When multiple concerns exist, one helpful approach to the determination of priority issues is the evaluation of keystone variables (Barnett, Bell, & Carey, 1999). Being "the one on which all others appear to depend" (p. 31), a keystone variable or behavior refers to those that, if changed, are likely to positively impact the largest set of other significant behaviors, perceptions or problem situations (Evans & Meyer, 1985). Examples of likely keystone behaviors for behavioral concerns include prerequisite communication skills, prerequisite social skills, compliance, and self-regulated behavior (i.e., being able to observe one's own behavior, make judgments regarding one's performance, and react). For academic concerns, examples of likely keystone behaviors include prerequisite reading skills and attendance. Given that successful interventions result in both beneficial effects *and* side effects (Barnett et al., 1999), identifying and addressing keystone variables may provide the most efficient means to achieve long-term resolution of problem situations. In determining targets for change, the following elements of keystone behaviors should be considered: (a) prerequisite skills or pivotal behaviors that can positively influence other important behaviors, (b) targets for change that will have maximum positive collateral effects, and (c) foundation skills needed for subsequent adapting to natural environments (Barnett et al., 1999).

Therefore, beginning with top priority concerns, specific target behaviors need to be defined for each. Each problem situation should be stated in concrete, behavioral terms that can be both observed and measured. In fact, research (Bergan & Tombari, 1976) has shown that, when problem situations were defined in observable and measurable terms, the probability of successful problem resolution was significantly higher. Conversely, when a medical model label or internal child attribution or explanation of behavior was introduced (e.g., child has ADHD), teachers take less responsibility for problem resolution and, overall, problem-solving efforts were less successful (Tombari & Bergan, 1978).

Whenever possible, specific target behaviors should be identified and defined in terms of positive replacement behaviors. That is, target behaviors should specify a positive or desired behavior to be increased rather than an undesired or inappropriate behavior to be decreased. Consideration should be given to a positive behavior goal for the student and the target for change stated as that desired behavior using observable and measurable terms.

Last, in addition to being representative of the problem area, specific target behaviors also should be socially valid and meaningful. That is, if these behaviors were changed, the expressed concerns would be alleviated. And, of course, the specific behavior(s) targeted for change must be alterable by and within the setting(s) of those participating in problem solving.

As a result of these considerations, the input of person(s) from the student's natural setting is critical at this and each of the remaining steps of problem solving.

Incorporated in all phases of collaborative problem solving, assessment may not be extensive during this phase but it does begin during problem identification. Because the concerns identified at this initial step of problem solving represent what is perceived to be the problem and what must be changed if intervention is to be regarded as successful, assessment may be used to gather information needed to define and clarify a student's current performance or skills, as well as to identify positive replacement behaviors. Current levels of behavior need to be measured and documented for all target behaviors. Baseline data are used to document that a problem situation exists by determining the discrepancy between current and expected levels of performance and, later, to provide a benchmark against which to judge the effectiveness of interventions. Particular *methods* of assessment that may used during problem identification include interviews with teacher, parent(s), and/or student, review of teacher records, review of work samples, direct observation, behavioral ratings, or curriculum-based assessment. Finally, the *outcome* of this step is specific delineation of the problem situation in terms of target behavior(s) and replacement behavior(s). Baseline data are collected to document current levels of performance on each and the mismatch between current and expected behavior.

Throughout problem identification, *collaboration* occurs among problem solvers as they elicit or provide information to clarify specific concerns and goals. In the role of consultant, one has the responsibility to facilitate the problem-solving process and completion of the steps. Additionally, consultants share openly their knowledge and expertise in related content areas to support the problem-solving process and guide good decision making. In fact, given that participation in problem solving is based on the knowledge and expertise that each can contribute, it is incumbent upon all participants to share the information they bring and to provide input throughout the process. That is, both educational support personnel and those directly involved in the problem situation such as the teacher, parent(s) and student have important information to share. Likewise, it is critical that all participants are given the opportunity to provide input to decision making and that, when they do, the information shared is valued and carefully considered.

In terms of decision making, the person(s) presenting the concern ultimately determines what problems are priorities and what targets to include. The consultant helps define and prioritize concerns and, as a collaborator, may provide another perspective that helps inform the decision. Thus, the primary ownership for defining the situation of concern rests with the person(s) experiencing the problem situation (e.g., the teacher, parent(s), and/or student). The likelihood that problem solving will be successful is increased when these participants are able to make fully informed decisions at each step of the process based on both their own knowledge and the expertise others have shared.

Common pitfalls in problem identification often are associated with a tendency to rush the process; that is, moving to other problem-solving steps before the problem situation is clearly and adequately understood. For example, participants sometimes begin problem solving around the first concern mentioned without exploring all concerns and deciding on the top priority problem situation. Relatedly, participants sometimes analyze in detail each concern as it is mentioned without having first identified and prioritized all concerns. The result is inefficient use of time and side-tracking of top priority concerns. Another common pitfall associated with problem identification is the tendency to move forward with vaguely defined concerns before target behaviors are operationally defined in clear, observable, and measurable terms. Rather, problem situations sometimes are identified using child deficit or diagnostic labels (e.g., ADHD, oppositional) or terms that remain vague and too global (e.g., unmotivated, reading problem). Furthermore, sometimes the behavior(s) targeted for change are not alterable. Finally, a common pitfall at this step is that one person decides on the top priority concern, target(s) for change, and/or replacement behavior(s) while others do not agree with or even know of the decision. This especially is a problem when someone other than those responsible for implementation makes a unilateral decision.

Problem Analysis: Why is the Problem Situation Occurring?

Determining why the problem situation occurs corresponds to the second step of problem solving: problem analysis. In answering questions about why a student does not meet expectations, the objectives are to understand the behavior in context (i.e., in the natural setting) and form a hypothesis about why the problem situation is occurring so that an appropriate intervention can be developed. If the interventions developed later are to match the bases of the problem, then the decisions made here obviously are important. The selection, use, and interpretation of assessment tools is critical in determining the validity and reliability of information derived from the problem-analysis phase of problem solving. The focus of our approach to problem analysis, consistent with IDEA 97, is on *direct* assessment of variables that help guide intervention design. That is, information is collected to answer specific questions in a direct and parsimonious manner. Assessment that does not have direct implications for intervention design is not used. Likewise, assessment need not be exhaustive. Rather, data should be collected using a process that is efficient and incrementally valid, with sufficient assessment data collected to make good decisions. Careful consideration must be given to both the type and amount of information needed to support problem analysis.

The processes of problem solving in general, and problem analysis in particular, are not necessarily linked to any theoretical orientation. Problem solving does provide a systematic process for addressing problem situations; however, the application of this framework can be useful in guiding service delivery premised on various theoretical models. Neither the process, the questions to be answered, nor the tasks that need to be accomplished at each step in the problem-solving process change according to one's theoretical orientation. However, the hypotheses and the answers that result will be different depending upon the theoretical orientation of problem solvers due to the way each conceptualizes the issues, gathers information, and interprets the information gathered. Given that we endorse an eco-behavioral orientation, our conceptualization of a problem situation and the factors causing it are not limited to sole focus on child variables. Rather, our analysis of the causes of the problem situation includes consideration of the skills and behavior of the student, teacher, and the environmental context (i.e., natural setting) in which the problem situation occurs.

The *questions* to be answered during problem analysis include: *Why does this problem situation occur? What factors contribute to the mismatch that exists between actual and desired levels of performance for each target behavior? What resources are available to help resolve this problem situation? What is the goal or expected outcome of intervention?* That is, what is the desired level of performance for each target behavior?

In order to answer these questions, all relevant factors related to the problem situation need to be analyzed—both those factors serving as obstacles inhibiting desired performance and those which might serve as supportive factors or resources in resolving the problem situation. In particular, attention should be given to variables that are directly relevant to the problem situation and alterable, and, therefore, possible areas for intervention planning. Certainly student variables related to performance would be considered; however, ecological variables that may affect target behavior also must be examined. Specifically, problem analysis for intervention design should include examination of natural setting variables (e.g., physical arrangement of classroom, proximity), instructional variables (e.g., patterns and routines), teaching strategies (e.g., specificity or frequency of directions given, feedback, task demands), and peer behaviors (e.g., interactions, supports). Complete descriptions of behavioral approaches to problem analysis can be found in sources devoted to elaborating these procedures (e.g.,, Daly, Witt, Martens, & Dool, 1997; Lentz & Shapiro, 1986; Martin & Pear, 1998; O'Neill et al., 1997; Shapiro, 1996; Tilly et al., 1998).

There are several general *considerations and tasks* for assessment at this step of problem solving. First, the situational context in which problems occur should be carefully assessed. For example, a functional analysis of the problem situation could be conducted to examine antecedents, behaviors, and consequences in relation to target behaviors for both actual and desired or replacement behaviors. Second, it is helpful to examine exceptions to the problem situation; that is, what are the environmental conditions when the target behavior does not occur or when desired behavior increases? Particular note should be made of conditions that can be altered as they may be useful variables for change in intervention design. Also as part of problem analysis, the mismatch between actual and desired behavior is analyzed to determine whether this problem situation represents a skill or performance deficit. That is, evidence would be examined to determine whether the student has not learned the skills required for the task, whether the student has the skills required but does not perform them, or both. Finally, resources or factors that are supportive of resolving the problem situation should be identified.

In general, the goal of problem analysis is to determine a functional relationship between student behavior and the conditions and circumstances under which the student is more and less likely to engage in the problem behavior within this environmental context (Greenwood, Carta, & Atwater, 1991). There are various types and approaches to assessment that might be used during the problem-analysis phase. Together participants must decide how best to answer the questions being asked about cause of the problem situation. As a rule, however, intervention-oriented assessment within a problem-solving framework is *direct* and *focused*, and includes multiple procedures and sources of information. That is, for the purposes of problem analysis, assessment should be conducted across multiple environments, multiple domains, and times, and use only relevant methods that inform intervention decision making. Examples of *methods* that are most directly useful for intervention purposes include systematic and directed observation, structured interviewing with those most familiar with the problem situation, functional behavioral analysis, curriculum-based assessment and measurement, behavioral rating scales, performance-based assessment, review of records, and review of permanent products such as work samples.

Last, *goals* should be generated as criteria for assessing intervention effect and stated in concrete, behavioral terms that are easy to measure. Specifically, what is the expected outcome of intervention? In order to meet expectations, what level of performance will the student need to do (or not do)? The target behaviors that will be increased and/or decreased and the desired level of performance should be clearly defined and agreed upon by all participants.

Collaboration as a method underlies all that is accomplished at this step. All questions generated and data collected must be developed collaboratively and must serve the purpose of helping to develop interventions to improve the situation. From a collaborative perspective on problem analysis, the responsibility for all decisions about what data to collect, how to collect it, who will collect it, and how to use it are shared. For example, classroom observations occur when there is a mutually agreed upon decision that more specific data are needed on a variable such as time on task, number of interruptions, or triggers for disruptive behavior. Together participants decide what information is needed and how to collect it. Thus, observation data are collected to answer a specific intervention-related question, not to "verify" a teacher observation or as a routine component of problem analysis.

Determination of who will collect what information is made with input from all participants, not based on assumptions regarding the role or prescribed responsibilities of any member of the problem-solving team but rather on logical distribution of labor, access, and/or availability. Often it will be the teacher and/or parent (i.e., person(s) primarily responsible for intervening) who will have the most thorough understanding of the problem and natural setting and the best access to the information needed. It is reasonable that the teacher and/or parent also assume an active role in collection and/or analysis of relevant data. If assessment is seen primarily as the domain of an "outside expert" such as the school psychologist, then the teacher or parent cannot be an active partner in problem analysis and a valuable resource is lost.

Just as the consultant does not serve in an expert role of deciding what information needs to be collected and how it will be collected, nor does the consultant "own" the assessment information and its interpretation once it is collected. Rather, it is the responsibility of all participants to contribute to the determination of information needed, to the collection of data based on logical division of responsibilities, and finally the use of data in decision making.

From information generated during problem analysis, the *outcomes* of this step will be (a) identification of the discrepancy between actual (present level of performance) and desired levels for each target behavior, (b) specific outcome goal(s) for the intervention that will follow, and (c) sufficient understanding of the problem situation and contextual variables to decide on an intervention plan to improve the situation. That is, based on the results of problem analysis, a hypothesis about factors related to the problem situation is outlined such that the expected nature of the relationship between the target behavior and variable(s) contributing to it is clear. Additionally, a statement about the desired goal or outcome of intervention is written using observable and measurable terms. It sometimes is necessary to refine the target behavior as part of this process.

Perhaps the most *common pitfall* associated with this step of problem solving is that problem analysis often is skipped entirely as collaborators rush to solve the problem. That is, after discussion of the problem situation itself, intervention strategies are suggested. Other common pitfalls of problem analysis include collecting assessment data that do not inform intervention design, forming hypotheses without data and/or no link to the data collected during problem analysis, or forming hypotheses about factors that are internal to the child or not alterable. Last, participants sometimes fail to state the outcome goal(s) in observable and measurable terms or to clearly specify the level of performance desired, making it difficult later to evaluate the adequacy of progress toward goals and intervention efficacy.

Plan Implementation: What Are We Going to Do to Resolve the Current Problem Situation?

Once the problem situation is clearly identified and understood, the focus of the problem-solving process turns to the task of designing an intervention to resolve it. Related to the task of intervention design, the next problem-solving step can be divided into several phases, each with its own questions to be answered and tasks to be accomplished. Specifically, these phases include exploring possible intervention strategies, selecting intervention(s), clarifying intervention and progress monitoring plans, and implementing the chosen intervention(s).

EXPLORE POSSIBLE INTERVENTION STRATEGIES

In posing the questions, *What needs to be changed* and *How is that going to be done?* the first phase of intervention design aims to explore possible intervention strategies that could be tried to improve the problem situation. In so doing, the intent is to generate and explore a range of alternative strategies for consideration by the person(s) who will be responsible for implementing the intervention. However, rather than generating a list of all possible strategies, efforts are made to identify a list of viable and well-supported intervention strategies for consideration.

To be effective, interventions must be logically related to the identified problem and to the reasons that the problem situation exists. Therefore, the exploration and selection of intervention strategies is based on specific information derived from problem analysis. By discussing the factors that contribute to the mismatch between current and expected performance, problem-solving participants begin to identify strategies for intervention. Consideration is given both to changing relevant context variables within the environment and to changing relevant skills or behaviors of the student, teacher, and/or others.

From a scientist-practitioner perspective, consideration of possible intervention strategies should be guided by reliance on strategies supported by intervention research. Although interventions must be individualized to fit a particular situation, the literature on academic and behavioral interventions and effective classroom instruction and management can provide a pool of strategies that have demonstrated effectiveness for relevant problem situations.

Additionally, when identifying strategies, participants are encouraged to think creatively (e.g., use of peers, self-management, other adults) and beyond thinking of an intervention as a place (e.g., Title I, resource room). At the same time, it is important to explore interventions that are feasible in the given situation. That is, intervention strategies should consist of *actions* that participants can either prepare for or begin implementing tomorrow. Intervention planning focuses on *what* specifically will be done to address the problem situation.

Finally, all participants assume responsibility for contributing ideas and considering options so that the process remains collaborative. Instead of presenting "solutions" for approval, participants offer *ideas* for consideration. Each has the responsibility to contribute his or her knowledge and expertise so that together all participants can consider and evaluate alternatives. For example, the persons most familiar with the problem situation and natural setting will share ideas based on their familiarity and experience with both. School psychologists and other professionals with knowledge of empirically supported interventions in relevant content areas will share that expertise.

SELECT INTERVENTION STRATEGIES

From among the many alternatives considered, specific intervention strategies must be chosen and an intervention plan outlined. Answers generated to the questions posed in previous steps are used to respond to the *question* that must be answered at this phase in the problem-solving process: *What intervention(s) should be tried to improve the problem situation?*

With regard to the *task* of selecting intervention strategies, there are several important issues to be considered. First, consistent with the notion of collaboration, responsibility for selecting an intervention strategy must rest with the person(s) who eventually will implement it. Given the collaborative nature of the problem-solving process, all participants share responsibility for generating and evaluating possible intervention strategies. However, because the person(s) who are most directly involved in the problem situation assume primary responsibility for plan implementation, they are given final choice in the selection of intervention plans. Clearly, they are in the best position to evaluate their ability and willingness to implement a proposed intervention. Moreover, if an intervention is unacceptable to the person who is to implement it, it is unlikely that it will ever be implemented as intended.

Of course, an important consideration relative to the task of selecting intervention strategies is the likelihood of success in changing this problem situation. With this in mind, evaluation and selection of the strategies that will comprise an intervention plan should be based on and incorporate the elements of strong interventions (Lentz, Allen, & Ehrahrdt, 1996). Defined as the "weakest that works" (Yeaton & Sechrest, 1981), a strong intervention includes effective instructional practices such as modeling, practice and performance feedback, frequent opportunities for the student to respond and practice replacement behaviors, feedback about performance and progress toward goals, error correction procedures, and contingencies for accurate performance.

Additionally, the selection of intervention strategies includes consideration of the findings from problem analysis to determine what should be changed and what can be changed. With a focus on "alterable" variables, the selection of interventions should consider what are the most natural, least intrusive, and most effective strategies for accomplishing change. That is, to what extent do these strategies fit with current classroom routines and teaching practices? What is the least amount of effort needed to get the desired amount of change? What, if any, positive effects are likely to result for other students and the teacher? In judging the potential efficacy of an intervention plan, consideration also is given to issues of feasibility, including the availability of resources. In sum, for the purposes of intervention design, participants consider information gathered during earlier steps of problem solving and empirical data from intervention research as the basis for generating, evaluating, and selecting intervention strategies. Those selected are combined to outline a strong intervention plan.

CLARIFY INTERVENTION AND PROGRESS MONITORING PLANS

Once intervention strategies have been selected, it is important to clarify all aspects of the procedures. In particular, all participants should agree on a written action plan that specifies (a) every component of the intervention plan, including progress monitoring, (b) person(s) responsible for each component of the plan, (c) setting(s) where the intervention will be conducted, and (d) beginning and review dates. Simply stated, the action plan needs to answer the *question* of *How will the intervention occur to improve the problem situation?* by considering who will do what when, where, how, and for how long.

To aid with clarification of the intervention plan and ultimately with its implementation, steps should be delineated or "scripts" developed as procedural checklists outlining major components of the intervention. They serve a useful function in communicating to all participants what the intervention entails and the responsibilities of each person. During plan evaluation, scripts also will be used to evaluate and document that the intervention was effective, and/or make needed modifications. A script outlines in sequential order all major intervention components in either a table or list form. Steps should be specific, detailed, observable, and measurable such that someone else can implement them. In front of each component of the plan, space is provided and used to check off as it is completed; also, space is provided for the date of implementation to be written.

Also clearly outlined as a portion of the intervention plan are procedures and a schedule for monitoring progress toward goals. Specifically, participants need to answer the important *questions* of *How will we know that the intervention is working?* and *How will we show others that the intervention is working?* In addition to establishing a brief repeated measure to assess target behaviors, a progress monitoring plan must include a timeline for intervention, goals or criteria for performance, and measures of both intervention adherence and efficacy. In addition, participants should determine when progress will be monitored and intervention results graphed, and by whom. A decision-making system that allows for interventions to be changed when they do not produce the desired outcome should be specified a priori.

IMPLEMENT INTERVENTION PLAN

The primary responsibility for implementation of the chosen intervention plan is assumed by the individual(s) (e.g., teacher, parent) who spends the most time in the setting(s) where interventions are being implemented rather than by educational support personnel such as school psychologists. However, it is the responsibility of *all* participants during the implementation phase to provide ongoing support for the intervention plan and their collaborators. In our experience implementing collaborative problem solving in schools, collaboration is most evident when all of the individuals who helped to develop the intervention also have a role in its implementation. For example, the teacher could direct implementation of the instructional strategy; the school psychologist could help set up the data monitoring plan, direct data collection, and graph results; the student could chart and self-monitor goal attainment; and the parents could reinforce goal attainment through rewards at home. The *question* to be answered at this phase in the problem-solving process is: *How can we best support the intervention and the intervener(s) during implementation?*

In response to this question, the *tasks* to be accomplished include providing ongoing support and systematic follow-up with intervention implementation. For example, it is important to provide those participants directly involved with implementation with encouragement and positive feedback for their efforts. Additionally, support may be needed in gathering resources and collecting data. To ensure that interventions are being implemented as outlined, it may be necessary to support the intervention by trouble-shooting with the intervener(s), and providing technical assistance with intervention procedures and/or monitoring of intervention adherence.

Common pitfalls can be found at each phase of plan implementation. For example, when exploring possible interventions, the strategies considered may not relate to information derived from problem identification or problem analysis, or build on intervention research or empirical data. Likewise, interventions may be specified in terms of an existing program or a particular person or place, not as actions to be taken to address student needs. When selecting the strategies for intervention, one person may outline a plan and presents it to the others for their approval. Instead, problem solvers should consider the alternatives and collaboratively decide on a plan considering input and ideas from all participants, especially those who will be responsible for implementing them. With regard to clarifying plans, participants often fail to outline intervention plans in sufficient detail and in writing. Similarly, progress monitoring plans may not be clearly delineated and written. During implementation of the intervention plan, participants must take care to provide sufficient time for implementation and support for those who are responsible for implementing the intervention.

Plan Evaluation: Is the Intervention Plan Working or Does it Need to be Changed?

In the problem-solving approach, an intervention is treated as a testable hypothesis, not a known solution. As such, assessment is an ongoing process and progress toward attainment of desired outcomes is monitored continually. After giving interventions sufficient time to be implemented, participants evaluate data regarding target behaviors and make decisions regarding the adequacy of progress made toward each goal. In addition to judging the effectiveness of an intervention plan, participants also evaluate outcomes in terms of the acceptability of the plan to those most directly involved and the adherence of intervener(s) to the plan as outlined.

The principle *question* to be answered during plan evaluation is, *How well is the intervention working?* Depending upon the answer received, follow-up questions need to be asked. Specifically, if the goals of the intervention are met, the focus of questions that follow will address issues in maintenance and/or generalization. For example, *Is the problem resolved or is there a need to continue an intervention? How will the intervention be faded in order to maintain the improvement?* and *How can the intervention strategies be applied to other settings in which this problem occurs?* If intervention outcomes are not satisfactory, then it will be necessary to answer questions such as, *Is it certain that the intervention plan was implemented consistently as outlined?* and *What information was missed during problem analysis?*

To decide whether the intervention plan is working, problem solvers need to undertake several *tasks*. Specifically, the data collected through ongoing assessment need to be examined to determine if the progress toward meeting goals is adequate. Consideration is given to both the demonstrated effectiveness and acceptability of the intervention. In evaluating intervention outcomes, evidence of adherence to the intervention plan also must be examined. Participants need to determine if the intervention was consistently implemented as outlined, discuss any problems with or unusual occurrences during implementation, decide if more time is needed, and/or decide if any changes are needed.

Based on the evaluation of the adequacy of the current intervention strategies for meeting goals, problem solvers are left with one of several decisions to make. Specifically, if the intervention has been successful, it will be necessary to decide whether or not to (a) continue with the current intervention plan, (b) outline strategies to phase out the current intervention procedures, with consideration for generalizing to alternative settings or target behavior(s) or for maintenance within the natural setting, or (c) address the next goal.

However, if it is decided that the interventions have not been effective in producing the desired changes in the problem situation, it may be necessary to strategically return to an earlier step in the problem-solving process. If so, the tasks facing participants include reconsidering the questions addressed in earlier steps, such as target behaviors, situational variables contributing to the problem situation, or the nature of an intervention strategy. Alternatively, if the outcomes of an intervention plan are not effective, it may be necessary for participants to pursue more in-depth or extended problem solving. That is, it may be necessary to access additional resources and supports by taking the problem to a higher level on the continuum of service delivery options (e.g., request consultative assistance at group problem-solving level rather than at individual level).

Consistent with a problem-solving approach, progress toward desired outcomes is monitored through ongoing assessment. Data are used to determine whether interventions are working, whether goals are being met, or if the intervention plan needs to be changed. Based on the information derived from assessment data, all participants work cooperatively to evaluate outcomes, and decide if and how intervention plans may need to be modified in order to enhance progress. Having agreed during the initial stages about the definition of the problem situation and which behavior changes would indicate improvement, participants should find these questions easy to answer.

Common pitfalls at this step of problem solving occur when decisions are made without adequate data. For example, participants may evaluate the efficacy of an intervention without progress monitoring data or evidence that data were collected using technically adequate measures of target behaviors. Determination of intervention effectiveness may be considered without any evidence of adherence to the intervention plan. For example, participants may judge an intervention to be unsuccessful when, in fact, it was never actually implemented or was not consistently implemented as outlined. Finally, a common pitfall associated with plan evaluation is the failure of participants to plan for subsequent steps, including outlining specific action plans to address goals for generalization and maintenance.

Flexibility in Problem-Solving Sequence Implementation

Actual problem solving rarely proceeds in a sequence as orderly as described. Rather it often is necessary to move back and forth between steps or, sometimes, to strategically return to an earlier problem-solving step and re-work steps of the process as new information is gathered or communication among participants improves. Nevertheless, the model described provides a framework that may be used as a flexible guideline for ordering of steps, not as rigid sequence of events.

SUMMARY

Given our common interest in supporting and addressing the needs of students, it becomes incumbent upon us (e.g., school professionals, parents, community members) to work together to solve problems. Recognizing that each participant will make different contributions to the process, it is important to realize that each also enhances the probability of reaching an effective solution to a particular problem situation. For school psychologists, perhaps the most important contributions can be made through facilitating the process used to address student needs. Rather than directing our energy at producing the "right" answer, school psychologists can work to establish ongoing relationships with and among other concerned individuals. And, second, we have the expertise to guide the use of a framework that all participants can use in systematically addressing the problem situation. A collaborative problem-solving approach to intervention design provides a model that school psychologists can use effectively and efficiently to enhance student learning and behavior.

ANNOTATED BIBLIOGRAPHY

Friend, M., & Cook, L. (2000). *Interactions: Collaboration skills for school professionals* (3rd ed.). New York: Longman.
With an emphasis on interpersonal interactions among individuals and groups, this practical volume provides a detailed overview of collaboration skills. Both collaboration contexts and interpersonal skills essential to effective consultative problem solving--listening, communicating, questioning, framing statements, and providing feedback—are covered in detail with practical application examples and practice activities for each. This book is an excellent introduction for educators without specific training in interpersonal aspects of collaboration and a useful refresher for experienced school psychologists regarding communication skills as applied to collaborative problem solving.

Kratochwill, T. R., & Bergan, J. R. (1990). *Behavioral consultation in applied settings: An individual guide*. New York: Plenum.
Intended to be a skill-training guidebook for practitioners interested in learning a behavioral consultation approach to the design and delivery of behavioral interventions in applied settings, this book can be used independently or as supplement to a text by the same authors (Bergan & Kratochwill, 1990) and/or supervised training in collaborative problem solving. Objectives and procedures are detailed for each of the four stages in the problem solving process, along with some sample interview formats. The content presented in each chapter is expanded with examples and discussion of transcripts from consultation interviews, discussion questions, and self-quizzes.

Rosenfield, S. A., & Gravois, T. A. (1996). *Instructional consultation teams: Collaborating for change*. New York: Guilford.
Bringing together literature on school consultation and school change, this book provides an essential resource for professionals seeking to implement more effective consultation-based services in schools and ensuring that the services become established functions of the school system. Written with the needs of practitioners in mind, this book details the process and describes the important features of the school-based Instructional Consultation Team, including methods and instruments for evaluating student progress and system functioning. Additionally, it also provides detailed, practical information on achieving systemic and lasting change in practice.

Shapiro, E. S. (1996). *Academic skills problems: Direct assessment and intervention* (2nd ed.). New York: Guilford.

Effective collaborative problem solving for the purpose of intervention design requires that problem solvers have a strong foundation in direct, intervention-oriented assessment, knowledge of effective classroom interventions, and skills to systematically plan and monitor assessment and interventions. This book is an excellent source of extensive, detailed information on each of these topics, with a particular emphasis on academic skills assessment and intervention. Practical guidelines, steps to follow in the process, and coverage of the knowledge base in several areas important to understanding classrooms (e.g., ecological assessment, interviewing frameworks for focusing on academic variables) are included. Helpful information is included on several specific assessment and data monitoring strategies, including curriculum-based assessment.

AUTHOR NOTES

The conceptualizations and examples found in this book have been shaped by the influence of many colleagues, and we want to gratefully acknowledge their contributions to our thinking. These individuals include our colleagues at the University of Cincinnati, David Barnett and F. Edward Lentz, as well as our many skilled students and graduates, whom we thank for their contributions to how we view problem solving. We also are indebted to the many educators and parents we have worked with in schools who continue to teach us about practical implementation of collaborative problem solving.

We attribute the phrase "admiring the problem" to James Ysseldyke, from whom we first heard this term several years ago. We believe it accurately captures the essence of many of the activities of multifactored evaluation teams that focus on finding and documenting student deficits, which Seymour Sarason has referred to previously as a "search for pathology."

University of Wisconsin-Milwaukee

OVERVIEW

Consultation continues to be a major approach for providing psychoeducational services to children and adolescents. In fact, recent reviews of consultation suggest that it is becoming recognized as the most preferred and satisfying function of school psychologists (Gutkin & Curtis, 1999; Sheridan & Walker, 1999; Sheridan, Welch, & Orme, 1996). Three major models of consultation that are used most frequently include mental health consultation, organizational development consultation, and behavioral consultation, but many more have been identified (see Zins, Kratochwill, & Elliott, 1993). Although differences exist among these models, all emphasize problem-solving expertise of the consultee within a triadic relationship (consultant-consultee-child). The behavioral model of consultation emerged as an alternative to traditional service delivery approaches in applied settings (Reschly, 1988), and traditionally has strong ties to behavioral theory (e.g., Bergan & Kratochwill, 1990). Nevertheless, the model has expanded, and new names have been invoked to describe the evolution in thinking (see Gutkin & Curtis, 1999; Stoiber & Kratochwill, in preparation). We are using the term "problem-solving consultation" to replace the earlier term "behavioral" used in the title of this chapter, but other terms could be used as well (e.g., solution-oriented, ecobehavioral).

We also want to emphasize that consultation is distinguished from the assessment and interventions that are used as part of the problem-solving process. While behavioral consultation traditionally has been affiliated with behavior modification and intervention techniques from this theoretical school, a more current focus of problem-solving consultation is to use a wide range of assessment and intervention technologies from diverse theoretical origins (see Gutkin & Curtis, 1999; Sheridan & Walker, 1999). For example, school psychologists may apply more traditional behavioral principles and techniques in developing intervention programs and use behavioral methodologies to evaluate the effectiveness of these services (see Martens, 1993). Likewise, school psychologists also may apply valid instructional principles such as pause time, pacing, teacher feedback, and/or homework instruction when developing an intervention plan to enhance the academic performance of underachieving students (Gettinger & Stoiber, 1999). Within a problem-solving consultative approach, consultants may draw upon prescriptive or directive approaches at some times and mediation-oriented approaches at other times (see Gutkin & Curtis, 1999; Stoiber & Kratochwill, in preparation). By using this framework, problem-solving consultation can be either directive or non-directive, depending upon the issue being addressed and other considerations (e.g., degree of coordination necessary to implement a plan, time available to facilitate skill development in consultees, need to promote the consultee as a valuable co-constructor of knowledge). Whereas specific intervention strategies may vary across presenting problems, two identifiable features are most frequently associated with problem-solving consultation, namely, indirect service delivery and a problem-solving approach.

The most widely recognized feature of consultation is its *indirect service* delivery approach (Bergan & Kratochwill, 1990; Sheridan & Walker, 1999). Services are delivered by a consultant (e.g., school psychologist) to a consultee (e.g., teacher or parent) who, in turn, provides services to a child in the school or community setting. The indirect approach to service delivery generally is regarded as a distinct advantage of consultation, since it allows the psychologist to affect many more children than could be served by a direct service approach. The centrality of consultation in linking assessment and intervention practices is making consultative models increasingly prominent as a component of solution-focused service delivery systems (Stoiber, Kratochwill, Vanderwood, & Potter, 2001).

Consultation involves a collaborative relationship in which the consultant is viewed as a facilitator. Emphasis is placed on the collaborative *problem-solving process*, which occurs during a series of interviews and related assessment activities. Throughout this process, the psychologist's role is to elicit a description of the problem, assist in analyzing the problem, co-construct a plan for intervention, and monitor the program once implemented. The teacher's or parent's role is to clearly describe the problem, work with the child to implement the intervention program, observe progress, periodically evaluate the plan's effectiveness, and supervise the child's actions (Elliott & Sheridan, 1992; Stoiber & Kratochwill, in preparation). For the consultation process to be effective, both consultant and consultee should bring the following dispositions to the consultation process: (a) a sense of preparedness and clear expectations, (b) a willingness to participate actively and openly, and (c) a capacity to assume a proactive role.

BASIC CONSIDERATIONS

Problem-solving consultation has two important goals: (a) to provide methods for changing a child's behavioral, academic, or social problem(s), and (b) to improve a consultee's skills so the consultee can prevent or respond effectively to future problems or similar problems in other children. Given these goals, consultation can be both a proactive and a reactive service. Researchers indicate that consultation-based interventions often have changed children's problem behaviors successfully (Gresham & Kendall, 1987; Sheridan et al., 1996). However, the proactive goal of influencing a teacher's or parent's ability to handle future problems has not been observed consistently. The accomplishment of these goals requires consultees to participate in a general process for analyzing problems, which results in an effective plan to resolve the problems. Successful consultants must demonstrate expertise in both coordinating and facilitating the problem-solving process and in implementing methods for monitoring whether the intervention is working. Although competence in problem identification and plan implementation are necessary conditions of problem-solving consultation, they are not sufficient to facilitate effective consultative interactions. Integration of positive interpersonal skills and understanding with technical expertise are equally important to maximize consultant-consultee effectiveness (Stoiber & Kratochwill, in preparation). For example, characteristics such as acceptance through nonjudgmental statements, openness, non-defensiveness, and flexibility positively affect the interaction between consultant and consultee. In the remainder of this chapter, the basic components of problem-solving consultation, specific consultant-consultee relationship variables that may influence the consultation process, and use of consultation with teachers and parents will be discussed.

Structure and Process of Consultation

Consultation has been conceptualized as a series of stages that structure and focus the problem-solving interaction between a consultant and consultee (Bergan & Kratochwill, 1990; Stoiber & Kratochwill, in preparation). A heuristic five-stage framework for consultation begins with *initiating a consulting relationship*, *problem identification*, and *problem analysis*, progresses to *plan implementation*, and concludes with *plan evaluation*.

Consultation begins with the *development of a relationship* between the consultant and the consultee(s) (Stoiber & Kratochwill, in preparation). Collaborative consultants who develop positive working relationships with consultees may (a) experience less resistance to consultation process and intervention, (b) find their suggestions are readily accepted by consultees, (c) increase the probability that consultees will follow through on an intervention, and (d) increase the effectiveness of the consultation process for the consultee and client. During this stage, it is critical that the consultant and consultee have uncovered a shared need or goal to focus the consultation process and develop an intervention. It is also during this stage that the consultant discusses with the consultee the stages of the consultation process, consultant and consultee roles, and shared responsibilities and ownership of the consultation outcomes.

Problem identification is perhaps the most critical stage of consultation because it results in the design and implementation of an effective plan. Traditionally, in behavioral consultation the focus was exclusively on identification of a target problem and elimination of that problem. More recently, an emphasis has been placed on teaching social and academic competencies in addition to dealing with a target problem (DiPerna & Elliott, 2000; Stoiber & Kratochwill, 2000). The interview represents the primary assessment technology for defining the problem and developing an understanding of the needs in social and academic competencies, although numerous other strategies may assist in defining the problem or issue (e.g., tests, rating scales and checklists, functional assessment, direct observations). During the problem identification interview, the consultant and consultee focus on describing and operationally defining the child's behaviors that concern the parent/teacher. In consultation a "problem" is a relative concept that becomes operationalized when the parent and/or teacher report a significant discrepancy between the child's current and the desired levels of performance. The determination of whether a significant discrepancy exists is not examined initially; however, once the current and desired levels of performance are defined objectively, this significant discrepancy becomes the focus. This approach to problem identification is based on the assumption that problems are the result of unsuccessful or discrepant interactions between and among persons (e.g., child and teacher; child and parent; teacher, parent, and child). Functional assessment strategies may be conducted to focus attention on the academic and social competencies that need to be taught and on the ecological context surrounding the concern (Stoiber & Kratochwill, 2000). Thus, the psychologist and parent/teacher first analyze the target problem within the ecological context of the child and the child's interactions with the environment. When baseline data support the existence of the specific problem, the psychologist and parent/teacher begin to jointly identify variables that might lead to behavior change and problem resolution.

Problem analysis, the third major stage of consultation, focuses on the variables and conditions that are hypothesized to influence the child's prosocial and challenging behaviors. Problem analysis is a natural extension of the problem identification stage, in that it essentially begins with the challenging behaviors and prosocial competencies of concern and focuses on establishing functional relationships between it and the antecedent or consequent events. Figure 1 displays the steps from the Functional Assessment and Intervention System (Stoiber & Kratochwill, 2000) that features examples of functional assessment. Questions about who, what, where, when, and under what conditions or contingencies are all considered relevant, and generally facilitate a better understanding of the problem behavior. In many cases, the problem analysis stage will require the psychologist to collect additional data about the child's challenging behaviors and social competencies. Thus, problem analysis may enhance refinement and, consequently, redefinition of the problem and the factor(s) that influence it.

Plan implementation follows the problem analysis stage and has dual objectives of (a) selecting an appropriate intervention and (b) implementing the intervention. Procedural details are essential at this stage, such as assigning individuals to various roles, gathering or preparing specific materials, or training individuals to implement the plan. The selection of interventions traditionally seems to have been based on the reported or assumed effectiveness of a particular method. The design and selection of appropriate interventions should be based on empirically supportable interventions and requires attention to issues of intervention acceptability, effectiveness, and consultee skills and resources (Kratochwill & Stoiber, 2000; Stoiber & Kratochwill, 2000). Many consumers and providers of psychological services are also demanding that interventions also be acceptable (i.e., time efficient, least restrictive, fair, and/or low risk to the child) (Elliott, 1988a, 1988b). Likewise, interest in inter-

ventions that are consistent with the teacher's/parent's child management philosophy and compatible with existing resources and skills of the individual delivering the intervention have also gained recent consumer interest and empirical support (Witt & Martens, 1988). Plan implementation also involves discussing and actually carrying out the selected intervention. This substage may consume several weeks and is characterized by interactions between the parent/teacher and child. These interactions may occur through brief contacts in which the psychologist monitors intervention integrity and side effects (Gresham, 1989), and possibly brainstorms with the parent/teacher ways to revise the plan and its use. DiPerna and Elliott (2000) recently developed a series of Intervention Record forms for teachers, parents, and students. These Intervention Records are based on the effective teaching literature and provide respondents opportunities to indicate *How helpful?* and *How feasible?* and specific intervention tactics that are likely to be used with a given student. These intervention record forms are an example of trying to enhance the likelihood that the interventions selected are acceptable and will be able to be implemented by a consultee. The psychologist's role may also involve observations to monitor child and consultee behaviors or training sessions to enhance the skills of the individual who is executing the intervention plan.

Plan evaluation is the final stage of consultation with the objective of establishing a sound basis for interpreting outcomes of the intervention for the targeted problem and social competencies, and providing a forum for evaluating plan effectiveness. The rigor of evaluation involved in research may not be used consistently in practice, but good evidence to verify outcomes should be routine in case consultation efforts. Single-case study strategies provide one means for evaluating change in the child's progress (Kratochwill, 1985). When the reported discrepancy between the child's behavior and desired level of functioning is reduced significantly or eliminated, academic and/or social competencies have been acquired, and the intervention is acceptable to both the teacher/parent and the child, the consultant and consultee decide whether consultation should be terminated. Outcome criteria should include maintenance of the desired behavior over time and generalization across multiple settings and conditions. In theory, a consultative case is not concluded until the discrepancy between the child's existing and desired behavior is reduced substantively and an acceptable maintenance plan is in place. Criteria such as overall improvement in the quality of life (social and academic) can also be invoked but may require a developmental focus in consultation. Therefore, it is often necessary to recycle through previous stages of consultation and re-evaluate refined or newly implemented interventions.

In summary, problem-solving consultation is a model for delivering assessment and intervention services to children via teachers or parents through a series of structured meetings. A heuristic problem-solving framework provides structure for collecting information and affecting behavior change. Although the problem-solving structure is sequential and overt, it should not be interpreted as inflexible or irreversible. The activities of consultants and consultees are multifaceted, involving at least interviews, functional assessments, selection and implementation of interventions, and evaluation of the interventions. Such activities generally require several interactions between the consultant and consultee, as well as ongoing consultee and client collaborative interactions.

BEST PRACTICES IN THE DELIVERY OF PROBLEM-SOLVING CONSULTATION

As noted in the previous sections of the chapter, problem-solving consultation consists of a series of stages or phases that are used to implement the process of consultation. Each of these steps, with the exception of plan implementation, involves a formal interview with specific objectives to accomplish. Best practices in problem-solving consultation suggest that psychologists adhere to specific objectives and activities within each phase. The major components for each of these phases are outlined next.

Stage 1: Establishing a Consultant-Consultee Relationship

The interpersonal relationship between a psychologist and parent/teacher is assumed to play a major role in the use and effectiveness of consultation. Thus, as with psychotherapy, issues of trust, genuineness, and openness have been deemed important qualities for both consultants and consultees (Gutkin & Curtis, 1999; Martin, 1978). These human qualities are magnified in a consultative model of service delivery due to the predominance of an interview mode of information gathering and sharing. The dynamics of communication, both talking and listening, are the medium through which psychologists display their attitudes about parents and teachers. Personal characteristics, professional competencies, and modeling all are important elements in establishing and maintaining constructive and professional interactions.

Sensitivity to issues of importance to parents and teachers also contributes to the development of a positive consulting relationship. Variables commonly examined in intervention acceptability research (e.g., Elliott, 1988a; Witt & Elliott, 1985) and dimensions of helping emphasized by empowerment theorists (e.g., Dunst & Trivette, 1988; Witt & Martens, 1988) provide variables to consider consistent with consultation that are relevant to the enhancement of relationships with parents and teachers. For example, acceptability researchers repeatedly have found that administration/management time and fairness of the intervention are important themes virtually to all teachers, and non-aversive approaches to intervention are valued highly by most teachers. Work by empowerment theorists applied to consultation suggests that (a) help is more likely to be perceived positively if it is offered proactively, (b) competence within teachers is best promoted by building upon their existing child management strengths rather than remediating deficits, and (c) use of existing resources in the school environment is preferred over the intervention or purchase of new resources (Witt & Martens, 1988). Thus, it is concluded that effective consultants (a) overtly communicate awareness of these issues that are central to teachers' daily functioning and (b) act cooperatively to design interventions. Such consultative actions may overcome many potential sources of resistance.

Resistance is a topic of considerable concern to practitioners and researchers alike and often has been conceptualized as something bad that resides within a person or institution. As observed by Wickstrom and Witt (1993), such a view of resistance is overly simplistic and unnecessarily negative. Within the context of a consultant-consultee relationship, they define resistance as "including those system, consultee, consultant, family and client factors that interfere with the achievement of goals established during consultative interactions." Resistance, then, is "*anything* that impedes problem solving or plan implementation and ultimately problem resolution" (Wickstrom & Witt, 1993, p. 160). This definition stresses that resistance is part of a system context and is multidirectional; that is, it does not reside in only one part of the system.

Having reviewed the theoretical and empirical reports on resistance to intervention in both the psychotherapy and consultation literature, Wickstrom and Witt (1993) recommend two general tactics to respond to resistance. The first tactic they call "Joining the consultee" and the second tactic they refer to as "Emphasizing referent power." Joining the consultee involves understanding a consultee's attribution system for explaining a problem of concern and then using that attributional framework to build a link to an intervention. Emphasizing referent power involves a consultant working to become more similar to a consultee. This tactic can be accomplished by using non-authoritarian and non-coercive means of control, using cooperative modes of interaction, asking questions, and making suggestions for change in a tentative manner (Parsons & Meyers, 1984). Efforts to use the consultee's existing skills and preferences for interaction activities, thereby reducing the number of "new" aspects of an intervention, also is likely to make suggestions more acceptable, and thus less resisted.

Resistance at the system level requires that the consultant address a wide range of practical and logistical variables. For example, school psychologists must have the skills to consult and develop interventions, and this role will require training. Administrators must support the role of the consultant through public endorsement and resources. Alternate models of special education service delivery such as non-categorical approaches (see Reschly, Tilly, & Grimes, 1999) may need to be embraced by the district or even the state. This process will require considerable effort on the part of the psychologist to change the special education system.

In closing this section, it is appropriate to remember that "once the door to the classroom is closed, there is little that any of the educational specialists can do to insure the occurrence of any event that the teacher does not want to occur...." (Gutkin & Curtis, 1981, pp. 220–221). Hence, the interpersonal or therapeutic relationship skills of a psychologist are important to the delivery of consultation as is knowledge of assessment and intervention methods.

STAGE 2: PROBLEM IDENTIFICATION

Problem identification is achieved through an interview where the primary objectives are to specify the goals, assess the problem and academic and social competencies, and implement certain procedures. Consultation can involve a developmental or problem-centered focus. In developmental consultation the consultant establishes general, subordinate, and performance objectives. Usually these are obtained over a long period and in several series of interviews. In contrast, problem-centered consultation involves specification of problems that are specific and relate to one or a few primary concerns or goals. Relative to the developmental consultation process, problem-centered consultation is more time-limited.

Whether the nature of consultation is developmental or problem-centered, the psychologist needs to achieve clear specification of problems, competencies, and goals. Typically, this process involves generating precise descriptions of the student's behavior, carefully analyzing the conditions under which the problems occur, and establishing some indication of the level of persistence or strength of the problems. During the problem identification phase the goals of consultation should be established. One system that can be helpful to establish goals and benchmarks for goals is *Outcomes: Planning, Monitoring, Evaluating* (*Outcomes: PME*) (Stoiber & Kratochwill, 2001a). *Outcomes: PME* includes five steps that are featured in Figure 2. The system embraces a focused goal setting and goal attainment scaling framework in which up to three goals and corresponding benchmarks are established. The system also includes a convergent evidence scaling format so that multiple outcome measures can be examined for correspondence on intervention effectiveness. *Outcomes: PME* is a useful tool for structuring and facilitating productive problem solving in consultation.

The *Academic Competence Evaluation Scales* (ACES) (DiPerna & Elliott, 2000) and its corresponding intervention system, the *Academic Intervention Monitoring System* (AIMS) (DiPerna, Elliott, & Shapiro, 2000), is another example of an approach to assessment-intervention that is consistent with a consultative problem-solving model. The ACES-AIMS approach utilizes teachers as the primary assessment and intervention agent for children experiencing difficulties with academic skills (reading, language arts, mathematics, and critical thinking) and academic enablers (interpersonal skills, engagement, motivation, and study skills). Both the ACES-AIMS emphasize behavior rating and goal attainment scaling technology to identify and monitor behavior. Figure 3 provides an overview of the use of both the ACES and the AIMS to facilitate enactment of a five-step problem-solving process.

Another important objective is establishing assessment techniques. Together, the teacher and/or parent

Outcomes: PME Procedural Checklist
Check all steps completed

1 *Describe and establish baseline of the behavioral or academic concern.*

☐ 1. Behavioral or academic concern defined in observable, measurable terms.
☐ 2. Baseline established on behavioral or academic concern.
☐ 3. Situational analysis of concern conducted (e.g., routines, expectation–skill match, contingent relationships, adult/teacher support required).
☐ 4. Student and situational assets to build on identified.
☐ 5. Parental input about behavioral or academic concern obtained.

2 *Set meaningful goals and benchmarks.*

☐ 6. Goal statement focusing on controllable, measurable behaviors written.
☐ 7. Benchmarks specifying standard against which to compare and scaling format selected.
☐ 8. Target date for goal attainment established.
☐ 9. Standard or social-comparison criterion against which to measure progress selected.

3 *Plan the intervention and specify progress-monitoring procedures*

☐ 10. Intervention with empirical support or functional basis identified.
☐ 11. Intervention strategies/steps developed and reviewed with the change agent(s) or interventionist(s), such as parent, teacher, language specialist, psychologist.
☐ 12. Context, frequency, and resources needed to implement intervention determined.
☐ 13. Progress-monitoring procedures specified, including individual responsible for implementing progress monitoring and individual responsible for collecting progress-monitoring data.

4 *Monitor progress and analyze data.*

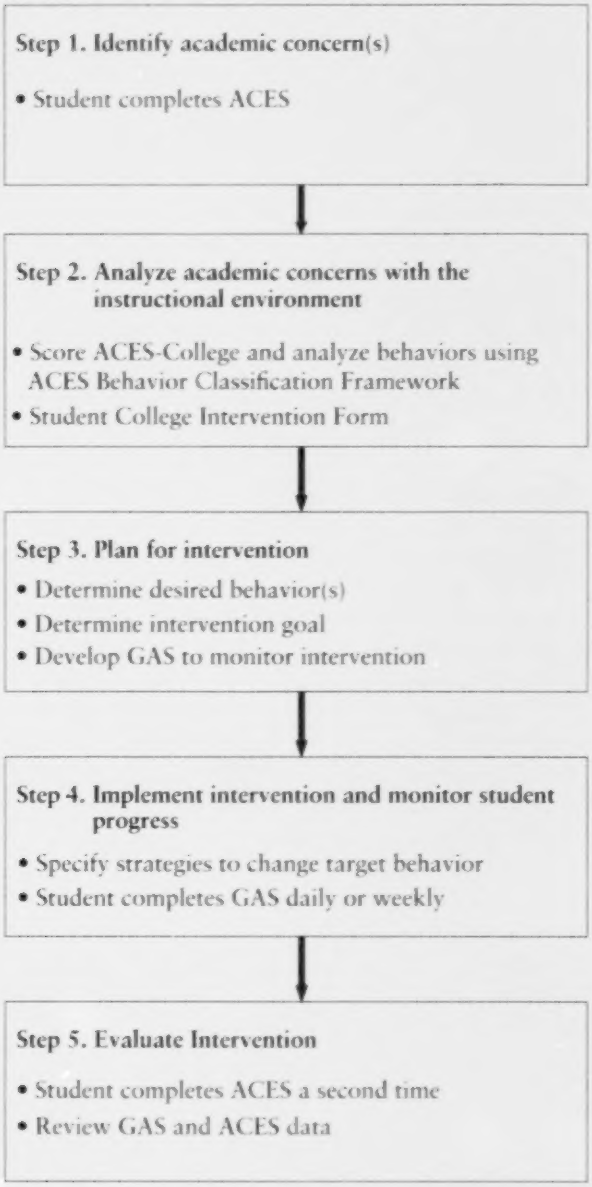
☐ 14. Goal scaled at beginning point, intervention with specified strategies implemented for specified time, goal scaled at ending point.
☐ 15. Progress-monitoring data and goal-attainment data plotted.
☐ 16. Evidence in support of child's progress documented.
☐ 17. Reasons for positive and/or negative progress review.

5 *Evaluate intervention outcomes and plan next steps.*

☐ 18. Based on convergent-evidence procedures, consensus on progress toward goal occurred.
☐ 19. Intervention-quality and intervention-integrity data reviewed.
☐ 20. Discrepancy between expected change and postintervention examined for significance.
☐ 21. Sufficient monitoring data and convergent data established.
☐ 22. Intervention goals and strategies revised, if indicated (e.g., due to poor progress).

and psychologist agree on the type or kind of measures to be used, what will be recorded, and how this process will be implemented. Finally, certain procedural objectives must be met during the problem identification phase. One of the first objectives involves establishing times, dates, and formats for subsequent interviews and contacts with the teacher and/or parent to examine procedural aspects of the consultation process. For example, the psychologist may agree to contact the teacher/parent weekly or biweekly to determine whether data are being gathered properly, or if any unique barriers have occurred. Witt and Elliott (1983) outlined nine components that facilitate the problem identification interview. These components have been revised and extended as follows:

Figure 3. The use of the ACES, College Intervention Form, and GAS within a five-step problem-solving process



Step 1. Identify academic concern(s)

- Student completes ACES

Step 2. Analyze academic concerns with the instructional environment

- Score ACES-College and analyze behaviors using ACES Behavior Classification Framework
- Student College Intervention Form

Step 3. Plan for intervention

- Determine desired behavior(s)
- Determine intervention goal
- Develop GAS to monitor intervention

Step 4. Implement intervention and monitor student progress

- Specify strategies to change target behavior
- Student completes GAS daily or weekly

Step 5. Evaluate Intervention

- Student completes ACES a second time
- Review GAS and ACES data

Source: DiPerna and Elliot (2000).

1. Explanation of the purposes problem definition: The parent or teacher should be told what is to be accomplished during the interview and why problem identification is important. (Example statement: "I would like to talk with you a few minutes about John's challenging behaviors that bother you most. We will need to assess his behaviors, when and how often they occur, and what factors in your classroom [or home] influence them. We will also need to identify academic and social competencies that John needs to acquire.")

2. Identification and selection of challenging behaviors and goals: The parent or teacher should be asked to focus attention on the problematic aspects of a student's difficulties and positive goals. (Example statement: "Please describe exactly what John is doing that has caused you concern." "What social competencies could replace his problematic and challenging behaviors?") When multiple problems are identified, it is necessary to establish a priority. (Example statement: "Which of these concerns is most pressing to you now?")

3. Identification of frequency, duration, and intensity of positive and negative prosocial competency behaviors: After challenging behavior and prosocial competencies have been defined, it is helpful to assess their basic characteristics: How often they occur (frequency), how long they last (duration), and how strong they are (intensity). (Example statements: "How many times did John cry last week?" "How long does each crying session last?" "What competency could John develop to replace his crying?") To interpret descriptions of frequency, duration, and intensity, the parent or teacher may be asked to compare the child's behavior with that of other children (social comparison). In addition, a psychologist should have knowledge of normative expectations to which the child's behavior can be compared.

4. Identification of the conditions under which the challenging behavior and goals occur: The assessment of environmental factors that occur in conjunction with a challenging behavior and goals are essential in understanding the problem. (Example statement: "How do you and the class react to John's crying?") Use of the Functional Assessment and Intervention System (FAIS) can help unravel many problems. This system involves the application of functional assessment to both challenging behaviors and social competencies.

5. Identification of the required level of performance: Obtaining a description of the behavior required of a student is as important as obtaining a description of the student's problem behavior. (Example statement: "What would you consider to be an acceptable frequency for this out-of-seat behavior?") Once a desired or expected level of performance is identified, it serves as a goal.

6. Identification of the student's strengths and social competencies: Learning what a child does well is often more useful than learning what a child does not do or does poorly. (Example statement: "What does John do best when interacting with his classmates?") Developing interventions that consider a student's strengths helps to increase the probability of a successful treatment. Again, the FAIS can be helpful in this regard.

7. Identification of assessment procedures: All interventions require some assessment or recording of behavior. Thus, a consultant should help a teacher or parent decide what, how, when, and where behavior will be recorded and who will do the recording.

8. Identification of consultee effectiveness: Given that one major goal of consultation is to enable a consultee to solve his or her own problems in the future, it may be necessary to teach or model problem-solving skills and enhance the consultee's confidence in his or her ability to solve problems. The goal obviously is for the consultant to be helpful to the consultee. To accomplish this goal, Witt and Martens (1988) advocate an empowerment, rather than an advice giving, philosophy of service for consultants. However, an empowerment philosophy assumes consultees basically are skilled individuals who can become more capable of solving their own problems by knowing what resources are available and how to gain access to them (Dunst & Trivette, 1988). If the consultee does not have the skills to provide services to the client, then these skills should be taught or other intervention options considered. One can determine the consultee's potential effectiveness by asking about how similar problems have been handled in the past, assessing what methods the consultee already has used to remediate the target problem, and judging whether the consultee is self-reliant or dependent on others for support (Meyers, Liddell, & Lyons, 1977). The AIMS Teacher Intervention Record form mentioned earlier is a useful tool for operationalizing this component of the problem identification interview.

9. Summary of the interview: The final step in the problem identification stage should include a summary of the important points discussed and a review of the problem definition. This summary should include a statement of the specific challenging behavior(s) or clarification of any further assessment necessary to refine the goals.

STAGE 3: PROBLEM ANALYSIS

After baseline data are collected on the areas of concern, the psychologist and teacher/parent meet to decide jointly on factors that might lead to some resolution of the problem. In this regard, the consultation process will focus on student, parent/teacher, and general environmental variables that may be of relevance.

The problem analysis interview includes five major steps: (a) choosing analysis procedures, (b) determining the conditions and/or skills analysis, (c) developing plan strategies, (d) developing plan tactics, and (e) establishing procedures to evaluate performance during implementation of any intervention program. Within the context of these phases, the psychologist might first analyze the factors that lead to potential solution of the problem and then develop a plan to solve the problem.

The psychologist focuses on conditions that facilitate attainment of the mutually agreed upon goals. Generally, the following steps are necessary:

1. Specifying whether the goal of intervention is to increase, decrease, or maintain behavior and determining what social competencies will be targeted.

2. Identifying setting events and antecedent/consequential conditions associated with behavior.

3. Determining what current conditions affect the behavior by comparing the existing situation to related research findings.

4. Identifying conditions not currently associated with behavior, but which nonetheless could influence solving the problem.

Through mutual problem-solving efforts, the psychologist and teacher/parent must analyze the kinds of child skills necessary to achieve the goals of consultation during the problem analysis phase. This process includes analyzing skills that the child does not possess, and can include both academic and social performance. Basically, the psychologist must work with the teacher/parent (and child if possible) to identify psychological and educational principles that relate to attaining the goals of consultation. It is beyond the scope of this chapter to outline these procedures in great detail. Rather, the reader is referred to a number of sources that can be useful to analyze overt behavioral and cognitive features that relate to instructional and social functioning (e.g., Bergan & Kratochwill, 1990; DiPerna, Elliott, & Shapiro, 2000; Stoiber & Kratochwill, in preparation).

The outcome of successful problem analysis is a plan to put into effect during the intervention implementation process. Development of this plan includes first specifying broad strategies that can be used to achieve the mutually agreed upon goals. The plan typically indicates *sources of action* to be implemented. Second, plan tactics are used to guide implementation of the strategy and outline principles to be applied during the intervention. For example, if reinforcement strategies are to be used, the person responsible for carrying out the plan and the conditions under which they will occur should be specified. During this phase psychologists might also assess treatment acceptability prior to its implementation. A number of scales have been developed for assessment of pretreatment acceptability, and readers are encouraged to consult this material (Elliott, 1988b; Witt & Elliott, 1985). Appendix A includes copies of two scales that can be used in the assessment of treatment acceptability.

Finally, during problem analysis the psychologist and teacher/parent must establish performance and assessment objectives that will be used during plan implementation. Typically this procedure follows from a conditions analysis and involves specification of an assessment procedure previously used during baseline. For example, when plan implementation involves skill development, some agreed upon format for collection of data on performance related to the final objectives achieved is necessary.

STAGE 4: PLAN IMPLEMENTATION

The fourth stage in problem-solving consultation involves implementing an intervention plan. Some initial activities are necessary during the plan implementation process and involve ensuring that the intervention is likely to succeed. In this regard, the psychologist should maximize the probability that the intervention plan is put into effect by the teacher/parent and/or child during this part of the consultation process. This step will require collaborative decisions regarding role assignments, material assembly, and skill development, as needed during the process. Although there is no formal interview during the plan implementation phase, it is the responsibility of the psychologist to monitor the implementation of the intervention and work with the teacher/parent to revise procedures during plan implementation, if it is determined necessary. It also may be desirable for the consultant to observe the child and/or teacher or parent to monitor behaviors and determine the need for subsequent revisions in the plan.

During plan implementation the three major tasks that must be accomplished include skill development of the consultee (if necessary), monitoring the implementation process, and plan revisions. Typically, the psychologist must determine whether the teacher/parent has the skills to carry out the plan. If skill development is required, then the consultee must be offered some type of training or guidance. This training might be offered through direct instruction of the consultant, modeling the intervention by the consultant, videotape and self-instructional materials, or through formal training offered by others.

A second task is to monitor data to determine if assessment is occurring as intended. Consultee records usually are examined to assess child outcome. This process usually will indicate to the psychologist when data are being gathered, how the performance of the child is being assessed, and what behaviors are being observed. It may also help the psychologist to determine whether the plan is actually proceeding as designed. If little progress is observed, then it is advisable for the psychologist to meet with the teacher/parent and revise the plan accordingly.

Monitoring plan implementation generally occurs in two ways. First, the child's behavior is monitored on an ongoing basis by the teacher/parent. This progress monitoring is a continuation from the problem identification and problem analysis phases of consultation. A second type of monitoring activity involves an evaluation of the strategies that are associated with the plan implementation itself. It is essential for the psychologist and teacher/parent to ensure that the plan agreed upon is being carried out as designed. The psychologist may choose to monitor plan implementation and integrity by discussing the intervention plan with the teacher or parent. A second procedure that can be used to complement this strategy is to actually observe the plan in operation or to get the consultee to report integrity data periodically (Gresham, 1989). It is acknowledged that various individuals might serve in the role of intervention implementors. Nevertheless, it is very likely that the psychologist will use a variety of procedures to facilitate plan implementation that are compatible with resources and responsibilities in the school or setting.

Finally, changes should be made in the plan when necessary. If the child's behavior is not changing in the desired direction, then plan revision should occur. Generally, this outcome will require that the psychologist and teacher/parent return again to the problem analysis phase to further analyze variables such as the setting, intrapersonal child characteristics, skill deficits, or social competencies. Likewise, it may be necessary to return to the problem identification stage if it is determined that the nature of the problem has changed.

STAGE 5: PLAN EVALUATION

Plan evaluation is implemented through a formal plan evaluation interview and typically is undertaken to determine whether the goals of consultation have been obtained. The process of evaluation includes assessment of goal attainment, plan effectiveness, and implementation planning.

The first major step in plan evaluation is to decide whether the actual goals previously agreed upon have been obtained. This decision is determined through discussion with the consultee and observation of the client's behavior. *Outcomes: PME* can be very useful to make decisions about the goals of consultation and can be continued during this phase. The process of evaluating goal attainment first was initiated during problem identification where the objectives and procedures for measuring mastery were specified. If *Outcomes: PME* was used, then specific benchmarks for each consultation goal were indicated. The data gathered since the problem identification phase should provide some evidence as to whether there is congruence between objectives and the problem solution. Basically, this step occurs on the basis of the data collected, but additional strategies might be invoked as well, such as social validation criteria specified in *Outcomes: PME*. That is, the psychologist will want to know whether the child reached some clinically established level of change and whether the intervention program brought the child's performance within a range of acceptable behavior as compared with normal or typical peers. Determination of the congruence between behavior and objectives generally leads the psychologist to conclude that no progress was obtained, some progress was made, or the actual goal was obtained.

The mechanism for evaluating plan effectiveness can occur through one of several case study strategies that have been used frequently in single-case evaluations (Kratochwill, 1985). In this regard, a variety of clinical design procedures might be implemented to facilitate decisions regarding progress in the consultation process. Again, it is beyond the scope of this chapter to outline these procedures in detail. Instead, the interested reader is referred to a primary source where these designs are reviewed (e.g., Hayes, Barlow, & Nelson-Gray, 1999). The recommended strategies basically involve a simple time-series design that includes an A/B format.

Advances in the evaluation of intervention effects and consultation outcomes continue to appear in the research literature. Several of these advances have been used in the evaluation of community mental health services and supplement the case study and social validation strategies that have traditionally been used by consultants. Two of the most practical strategies are Goal Attainment Scaling (see Stoiber & Kratochwill, 2000) and the Reliable Change index (RC) Jacobson, Follette, & Revenstorf, 1984). Both of these evaluation strategies are used in the ACES-AIMS approach to academic interventions and can be generalized broadly.

Briefly, there are several different approaches to using a goal attainment framework. The basic tactic, however, is one where a consultee would be asked to describe five to seven levels of intervention outcome. The most unfavorable outcome described is given a -2 or -3 rating, the expected outcome is given a 0 rating, and the most favorable outcome is given a +2 or +3 rating. Ratings of -1 to -2 and +1 to +2 are ascribed to benchmark descriptions of outcomes that are situated between the most unfavorable and expected outcome and the most favorable and expected outcome, respectively. *Outcomes: PME* can be used to get daily or weekly measures on intervention progress, as well as final outcome perceptions from a consultee. *Outcomes: PME* is a sensitive system since both over and under attainment of objectives can be rated.

The RC evaluation method was first proposed by Nunnally and Kotsche (1983) and is defined as the difference between posttest scores and pretest scores divided by the standard error of measurement. Typically an RC of +1.96 or greater is considered statistically significant, and more importantly it is inferred that the intervention produced a reliable change in a person's behavior. The RC is designed to be used with data from rating scales or individualized tests where total pretest and posttest scores can be calculated. However, this metric for reporting intervention outcomes is affected by the reliability of the dependent measures. Gresham noted that the dual criteria of social validation (social comparison and subjective evaluation) and RC should provide practitioners with a means for documenting educationally and statistically significant changes in behavior.

Once it has been determined that the problem has been solved, post implementation planning occurs to help ensure that the particular problem does not occur again. There are some alternatives available for the psychologist and teacher/parent in designing post implementation plans. One strategy is to leave the plan in effect. Typically, however, a plan that is put into effect will need to be modified (another alternative) to facilitate maintenance of behavior over time. There is considerable evidence in the intervention literature that specific tactics are needed to facilitate maintenance and generalization of behavior, and these tactics must be accomplished during this phase of consultation. Generalization may occur naturally, but more likely it will need to be programmed. Several factors have been identified that have a bearing on the generalization of skills (Haring, 1988; White et al., 1988). Table 1, from White et al. (1988), lists the strategies for facilitating generalization along with a definition and example. The table is based on the seminal work of Stokes and Baer (1977) and can serve as a useful guideline for consultants.

Another major objective that should occur during the plan evaluation interview is discussion of post implementation recording. Generally, this procedure refers to the process of continuing record keeping activities to determine whether the problem occurs in the future. Usually, the psychologist and teacher/parent select periodic measures that are convenient to use and may maintain specific features of the original plan to facilitate this data collection process. Best practices also suggest that the psychologist consider conducting post-plan implementation acceptability assessment as well. These procedures can be implemented informally or more formally with acceptability instrumentation (Elliott, 1988b). Finally, the teacher/parent should notify the psychologist of any reoccurrence of the problem behaviors that might be indicated. These usually can be brought to the psychologist's attention and specific tactics set up to establish a system to analyze the problems.

Consultation With Teachers and Parents

Traditionally, psychologists have implemented consultation with classroom teachers in an effort to establish intervention programs in the regular classroom and thereby reduce the number of placements in special education programs. This emphasis on prevention and direct intervention with teachers advanced the development of a knowledge base to prevent more serious behavioral problems in children. Within the past decade, school-based consultation services have expanded to include work with special education teachers, particularly teachers of emotionally impaired children (Gable et al., 1998; Kratochwill, Sheridan, Carrington Rotto, & Salmon, 1991) and teachers from early intervention programs for preschool-age children (Gettinger & Stoiber, 2000). In addition, consultation also has been used successfully to remediate academic and socialization difficulties in school settings (Stoiber & Kratochwill, in preparation). Applications such as these have presented unique opportunities for school psychologists to increase contact with special education teachers while generally addressing more severe presenting problems in special needs children who often experience multiple difficulties. Hence, the role of consultant has become increasingly specialized, with unique time demands and intervention needs that may vary according to the child's presenting problems and the teacher's level of expertise in areas such as behavior management and individualized instruction.

Table 1. Strategies for facilitating generalization

Strategy	*Definition*	*Example*
Train and hope	Providing simple instruction and then "hoping" that generalization will occur. Actually the absence of any special strategy.	Three preschool boys who were blind and severely or profoundly retarded were taught to reach for noise-making toys always presented at the midline. None of the boys generalized to objects presented on the right or left.
Setting: Training in the natural setting	Training is conducted directly in at least one type of setting in which the skill will be used. Generalization is then probed in other non-training settings.	The social interaction skills of several individuals with severe handicaps were trained in the classroom and courtyard during class breaks.
Sequential modification	Training is provided in one setting and generalization is probed in other settings. If necessary, training is conducted sequentially in more and more settings until generalization to all desired settings is observed.[a]	One girl with moderate handicaps needed articulation training in three settings before generalizing to all remaining situations of interest; a second girl only required training in two situations before generalizing.
Consequences: Introduce to natural maintaining contingencies	Ensuring that learner experiences the natural consequences of a behavior by teaching a functional skill that is likely to be reinforced outside instruction; training to a level of proficiency that makes the skill truly useful; making sure the learner actually does experience the natural consequence; and/or teaching the learner to solicit or recruit reinforcement outside instruction.	Three teens with multiple handicaps and severely retarded were taught to use symbols and pictures to request objects. Generalization was encouraged by using objects that would be regularly encountered outside instruction, making sure the boys always carried their communication boards, and that someone would always be present to provide any requested items.
Use indiscriminable contingencies	If natural consequences cannot be expected to encourage and maintain generalization, then artificial consequences or schedules of natural consequences might be used. However, it is best if the learner cannot determine precisely when those consequences will be available, and so must behave as if they always are.	Two behavior disordered and five normal preschool children always generalized their interaction and study better when verbal praise by the teacher was provided after progressively greater delays, rather than immediately following each behavior.
Train to generalize	The learner is only reinforced for performing some generalized instance of the target skill. Performing a previously reinforced version of the response is no longer reinforced.	Four youths with severe retardation were taught to name specific items. Contingencies were then altered so they were only reinforced if they named untrained items. After three sessions, all youths generalized well to untrained items.
Antecedents: Program common stimuli	Selecting a salient, but not necessarily task-related, stimulus from the situation to which generalization is desired, and including that stimulus in the training program.	Stokes and Baer (1977) report a case in which an individual with severe retardation was taught exercise skills to facilitate integration in a physical education class. Music was played during the PE class, so music was also introduced into the individual's training sessions to make the two situations more similar.
Sufficient exemplars	A strategy similar to Sequential Modification, involving sequential addition of stimuli to the training program until generalization to all related stimuli occurs.[b]	An adolescent with severe handicaps was taught to name objects, and probed with other objects from the same class. Some objects required only a single exemplar to produce generalized naming, while other objects required five exemplars before generalization occurred.

(Table continues on the following page.)

Table 1. (continued)

Strategy	*Definition*	*Example*
Multiple exemplars	Several examples of the stimulus class to which generalization is desired are trained at the same time.	Three adults with profound mental retardation were trained in three types of exercise. Generalization occurred to a group exercise program and to two untrained exercises.
General case programming	The universe to which generalization is desired is analyzed, and representative examples of positive stimuli (stimuli in the presence of which the skill should be used), negative stimuli (stimuli in the presence of which the skill should not be used), and irrelevant stimuli (stimuli which should not affect skill use, but might inappropriately do so) are selected for training.	Six young men with moderate or severe retardation were trained on three vending machines that reflected the range of machine types found in the community. Good generalization was obtained to 10 untrained machines in the community.
Other: Train loosely	Settings, cues, prompts, materials, response definition, and other features of the training situation are purposely varied to avoid a ritual, highly structured, invariant program that might inhibit generalization.	Mothers were taught to vary the type of stimuli and reinforcers they used in working with their children's motor skills. All children learned their skills quickly and generalized well to another setting.
Mediate generalization	Teaching a secondary behavior or strategy that will help an individual remember or figure out how and when to generalize, or which will dispel the differences between the training and generalization situations.	Five adolescents with moderate or severe mental retardation were taught to self-instruct task completion using a picture sequence. They then used the self-instruction skill to generalize task completion of a new task with a new picture sequence.

[a] Stokes & Baer (1977) described this strategy as training in one situation and, if that fails to produce generalization, training in all remaining situations of interest. The more literally "sequential" nature of the procedure as described above seems better suited for describing current application of the strategy.

[b] Stokes & Baer used this label to describe the successive introduction of new stimuli or settings, but separating the two variations seems more advisable for the current study.

Note: Adapted from White et al., "Review and analysis of strategies for generalization." In N. G. Haring (Ed.), *Generalization for students with severe handicaps: Strategies and solutions* (pp. 15–51). Seattle: University of Washington Press. Copyright 1988. Reproduced with permission.

Although consultation with teachers to deal with problem reduction is an effective method of remediating school-based problems, this focus fails to address the broader context and focus within which the child's problems may occur. For example, a withdrawn child who exhibits an absence of peer interactions at school likely would be unable to develop and maintain positive social relationships with neighborhood peers. Focusing exclusively on this child's social withdrawal in the school setting through teacher-only consultation restricts conceptualization, analysis, and intervention of the problem to a single target domain and setting. The broader behavioral interrelationships across environments would not always be considered. First, consultation should focus on development of social competencies and not just the reduction of problematic behaviors (Stoiber & Kratochwill, in preparation). Second, problem-solving consultation should be extended to serve as a link among the significant settings in a child's life, primarily, the home, school, and community environments. This approach facilitates a comprehensive conceptualization of the problem while involving primary caretakers in the intervention process. In addition, although few investigators have assessed the generalization of intervention effects across settings, the potential benefits of broadening the focus of problem-solving consultation to encompass the interacting system in the child's life are apparent.

There are several methods that can be used to expand the scope of consultation. First, as we have noted throughout this chapter, the focus of problem solving needs to move beyond a target behavior focus where challenging behaviors are reduced to a focus that also includes building social competencies (Stoiber & Kratochwill, 2000). Table 2 provides an example of the social competency domains from the FAIS. During the problem analysis phase the consultant can ask teachers and parents to complete the Social Competence Performance Scale and target one or more of the domains for intervention. Similarly, on the academic side of functioning teachers and students could complete the *ACES* to target academic enablers or skills for intervention. Figure 4 provides an illustration of the ACES subscales.

Another method of expanding consultation services entails involvement of parent-teacher pairs in problem solving. In conjoint consultation, parents and teachers together serve as consultees (Sheridan & Kratochwill, 1992; Sheridan, Kratochwill, & Bergan, 1996). The primary goals of this approach are to bridge the gap between home and school settings, maximize positive intervention effects within and across settings, and promote generalization of intervention effects over time. Continuous data collection and consistent programming across settings also are inherent with this approach. Conjoint consultation has been found to be an effective method of service-delivery in enhancing social initiation behaviors across home and school settings (e.g., Sheridan, Kratochwill, & Elliott, 1990). Likewise, it has been demonstrated to be effective in enhancing the academic productivity of underachieving students (e.g., Galloway & Sheridan, 1994). Conjoint consultation also has been effective in decreasing the irrational fears of a kindergarten student and has been used to enhance the effects of parent training in managing the behavior of children diagnosed with attention deficit hyperactivity disorder (ADHD) across home and school settings (e.g., Colton & Sheridan, 1998; Galloway & Sheridan, 1994).

Use of problem-solving consultation also has been extended beyond schools to address problems with individuals other than teachers, such as parents. Parent-only consultation may be applicable when a child's problematic behaviors are observed predominantly in the home and/or community settings but are not evident in the school environment. For example, parent consultation has been used to decrease the noncompliant behaviors of school-age children whose difficult behaviors were displayed at home and in public places but were not observed in the more structured classroom setting (e.g., Carrington Rotto & Kratochwill, 2001). In addition, consultation with parents also has been advanced as a model of early intervention with the goal of decreasing noncompliant and aggressive behaviors of preschool-age children (Carrington Rotto & Kratochwill, 1994). In parent-only consultation, the traditional problem-solving consultation framework provides structure for involving parent(s) in the process of identifying and analyzing the problem, as well as observing and evaluating intervention effects over time. Use of parent training provides structure for teaching parents specific skills, which enhance plan implementation. Necessary preparations for plan implementation include teaching parents specific behavior management skills and ensuring that they are adept at imple-

Table 2. Social competence chart: Goals, sub-goals, and performance indicators

Social competence goal 1: Emotion regulation and self-control skills

Child will demonstrate an awareness of, and a sense of *personal* responsibility for his *or her* own feelings, thoughts, actions, reactions, and learning.

Social competence goal 2: Social awareness and group participation

Develop and maintain productive social relationships, including competence in understanding feelings in others, friendship-making, interpersonal conflict resolution, and being able to adapt and work cooperatively in group situations.

Social competence goal 3: Social decision making and responsible life choices

Develop ethical and responsible ways in making decisions, and developing positive goal direction, including those that influence attitudes, behaviors, and functioning in school but also can affect the decisions and responses one makes in their home and community settings.

menting these skills. Specific methods of promoting generalization of parent behaviors (i.e., skill implementation) across settings and situations to enhance specific child behaviors need to be implemented.

In sum, problem-solving consultation provides a useful framework for working within and between family and school systems. This systematic problem-solving approach may be conducted with teachers, parents, or teacher-parent pairs to enhance child functioning across home, school, and community settings. Together with parents and teachers, psychologists may develop and implement intervention plans to address diverse target problems in areas such as academic productivity, socialization, and behavioral difficulties. Future research should be directed toward replication of intervention effects with diverse student populations and further examination of alternative parent and teacher roles and levels of involvement in consultation.

Writing Consultation Case Reports

At various times during the course of consultation, the consultant may wish to formally communicate the results of the intervention program to the parent and/or teacher. Indeed, it is the ethical and professional responsibility of the consultant to ensure that information concerning an intervention is communicated in a valid, clear, and concise manner. Although a variety of traditional report formats exist (see Gelfand & Hartmann, 1984; Grimes, 1983; Martin, 1972; and Ownby, 1987 for overviews), the present format provides a conceptual scheme for reporting interventions that are compatible with best practices in consultation. The consultant, however, is advised to modify this format to accommodate personal preferences and meet specific institutional needs and standards. The reporting format that we present can readily be used for consultation activities that are part of a prereferral intervention or specialized programs that are part of multidisplinary or Individual Education Plan team follow-up activities.

The present report format represents an outline for describing the activities of an entire consultation program (see Table 3). If reporting information prior to completion of the plan, then only parts of this report would be appropriate. General characteristics of the consultation report include (a) Background Information, (b) Problem Definition, (c) Intervention Plan, (d) Plan Evaluation, and (e) Summary and Recommendations.

The section on *Background Information* includes demographic information describing the child and details regarding the setting in which the problem occurs. For example, the child's name, date of birth, age, gender, school, parents, address, telephone, and teacher should be specified. The consultant should also include a description of the family, siblings, socioeconomic status, peers, teacher, and any other ecological features that are relevant to the case.

Many alternative ways exist to define a problematic situation. For example, problem behaviors may be described at various levels of specificity. Alternatively, a problem situation can be conceptualized in terms of reducing negative behaviors or increasing social competencies. The purpose of the *Problem Definition* is to provide a description and rationale for the problem as it was defined by the psychologist (i.e., consultant) and teacher/parent during consultation. Information from the problem identification interview will be especially relevant. More specifically, details regarding the referral problem, target goal(s), desired outcome behavior(s), critical setting or situations for change, and a preliminary functional assessment should be included.

Discussion of the initial referral issue should indicate the referral source and a description of the problem and goals. The consultant also should note that consent for participation was obtained from the child's parents. An operational definition of the problem as agreed upon by the psychologist and teacher/parent should be described in terms of deficits, excesses, frequency, intensity, and duration. Specification of the target area(s) and a statement regarding desired outcome and goal(s) also should be included. In addition, the consultant should discuss the critical setting where the child's behavior was expected to change and provide a detailed description of the situations necessary for such a change.

Finally, a preliminary functional assessment should compare the antecedents and consequences surrounding the problem behavior and social competencies to those necessary for attainment of the desired behavior. This discussion should be based on assessment procedures such as interview, direct observation, and/or standardized rating scales and checklists. Hence, the consultant integrates the baseline data, observational data, and problem identification and analysis interviews to analyze the discrepancy between the existing behavior and desired behavior. A sample of each observational data sheet used during the case may be included in the report. A description of any intervention programs or procedures implemented during the process of consultation should be included in the *Intervention Plan*. The consultant should characterize the basic design of the plan according to variables such as the (a) time needed for implementation, (b) intervention agents, (c) criterion for delivery of procedures, (d) set-

Table 3. Outline for writing a consultation case report

I. *Background information*
  - A. Demographic information on the child
  - B. Ecological context of the problem

II. *Problem definition*
  - A. Referral problem
  - B. Target behaviors
  - C. Desired outcome behaviors
  - D. Critical setting/situations for change
  - E. Preliminary functional analysis

III. *Problem analysis*
  - A. Description of assessment or data recording procedures
  - B. Rationale for use of data collection procedures
  - C. Presentation and discussion of data

IV. *Intervention plan*
  - A. Evaluation design
  - B. Contingencies
  - C. Criterion for contingencies
  - D. Acceptability of intervention to teacher/parent and child
  - E. Personnel involved in intervention implementation
  - F. Setting and time
  - G. Resources
  - H. Procedures for promoting new behaviors
  - I. Procedures for increasing existing behaviors
  - J. Procedures for reducing interfering problem behaviors
  - K. Procedures for facilitating generalization
  - L. Treatment integrity checks

V. *Plan evaluation*
  - A. Change in behavior via direct observation
  - B. Change in teacher/parent performance ratings
  - C. Mainstreamed peer comparison
  - D. Outcome interview with significant adults
  - E. Intervention side effects

VI. *Summary and recommendations*
  - A. Summary of results obtained
  - B. Discussion of effectiveness
  - C. Suggestions for increasing program effectiveness
  - D. Suggestions for future follow-up

ting and time, and (e) resources or materials necessary. In addition, the consultant should specify clearly the procedures used for promoting new social competencies, increasing existing behaviors, and/or reducing interfering problem behaviors. A rationale describing why the particular intervention procedure(s) are relevant to the challenging behavior is essential. In some cases, an intervention "package" consisting of many specific techniques (e.g., feedback, reinforcement, modeling) may be used. Identification of the individuals who are responsible for implementing the integrity plan and a discussion of the degree to which the plan is acceptable to the teacher/parent and child also should be included. Finally, it is desirable to document the strategies used to facilitate generalization and to verify the intervention plan was implemented as intended.

This list is intended to serve as a resource and should be considered carefully. The consultant must determine the variables most pertinent to the specific case; thus, it may be necessary to generate additional dimensions that adequately describe the intervention. Likewise, some of the intervention variables listed may not apply to all cases. It may be helpful to use headings or an outline format similar to that in Table 3 to facilitate note taking during consultation interviews and post-intervention preparation of a clear and concise report.

A complete description of the *Intervention Evaluation Plan* should be provided, including methods used to evaluate the specific intervention components and document changes in the child's behavior. Especially relevant will be data from the plan evaluation interview. The psychologist should present the results of the program in the context of the data collected over the duration of the program and during the generalization or follow-up phases. For example, direct observations and ratings of the child's performance may provide documentation of intervention outcomes. In addition, the consultant may evaluate the performance of a typical peer for social comparison before and after the plan is initiated. At least one figure should be used to portray the data collected, and the psychologist should acknowledge any unique features of the data (e.g., absence, program not followed) or challenges that may have occurred. The consultant should also provide details regarding any unanticipated side effects which may have resulted from the intervention plan.

The *Summary and Recommendations* should begin with a brief overview of the results obtained and a rationale for program effectiveness or failure. Here it is important to make a judgment about whether change was produced at, above, or below expected levels. The consultant also should include suggestions for increasing the effectiveness of the program. Recommendations may provide suggestions for (a) future follow-up, (b) enhancing maintenance and generalization, and (c) subsequent intervention plans. These suggestions should identify the socialization agents (e.g., parents, teachers, peers) and relevant materials that may be useful for the child or intervention personnel in future work.

SUMMARY AND CONCLUSIONS

Problem-solving consultation may best be conceptualized as a five-stage approach that uses broad-based behavioral and collaborative methods as the basis for problem identification, analysis, intervention, and evaluation. The major features of consultation include its indirect service delivery approach and problem solving focus. Consultation has two principal goals. The first goal is to produce change in the child's behavior or to enhance social competencies indirectly through collaborative problem solving between a consultant (psychologist) and consultee(s) (e.g., teacher/parent). A second, yet equally important goal of consultation is to empower the consultee with skills that will enable future independent problem solving.

A growing body of research has accumulated on the positive outcomes of problem-solving consultation (Gutkin & Curtis, 1999; Sheridan et al., 1996). Additionally, the practice of problem-solving consultation is expanding rapidly. In particular, there is a strong movement toward problem-solving consultation in school settings to the exclusion of traditional refer-test-place practices (Reschly & Ysseldyke, 1995). This growing enthusiasm over the potential benefits of consultation is apparent in the numerous articles on the topic published recently in both the psychological and educational literature (Sheridan et al., 1996; Zins, Kratochwill, & Elliott, 1993). As psychologists have become interested in the integration of consultation with daily activities and child adjustment in schools and homes, questions regarding the process and outcome of consultation have surfaced. Studies have examined the application of interventions in consultation to achieve changes in behavior and compared the effectiveness of consultation to other forms of service delivery.

Specifically, research documenting the effectiveness of consultation has been organized around four areas of investigation: (a) outcome research, (b) process research, (c) practitioner research, and (d) training research (Gresham & Kendell, 1987; Sheridan et al., 1996). Research addressing outcomes of consultation document its effectiveness in remediating academic and behavior problems manifested by children in school settings (Bergan & Kratochwill, 1990; Sheridan et al., 1996). Likewise, these same studies suggest that changes result in the teacher's and parent's behavior, knowledge, attitudes, and perceptions. Although consultation traditionally has been directed toward a single client (i.e., teacher), it also has been applied successfully with parent groups (e.g., conjoint consultation). A collaborative problem-solving model whereby the consultant, teacher, and parents share information, value each other's input, and incorporate each other's perspective in developing the intervention plan is considered to afford the greatest benefits (Colton & Sheridan, 1998; Sheridan & Kratochwill, 1992).

Typically, process research has focused on problem identification, since the consultant's ability to elicit a clear description of the problem has been identified as the best predictor of plan implementation and problem solution (e.g., Bergan & Tombari, 1975, 1976). Studies in this area also have focused on comparing consultation effectiveness with other forms of service delivery (Medway, 1979). It remains difficult to draw conclusions from the studies addressing variables associated with the process of consultation due to limitations in scope, theoretical base, and research methodology (Gresham & Kendell, 1987).

Traditionally, studies on practitioner utilization have suggested that school-based consultation is a preferred activity for school psychologists (e.g., Gutkin & Curtis, 1981; Meacham & Peckam, 1978). Likewise, teachers and administrators view consultation as an essential aspect of school psychological services (Curtis & Zins, 1981). Most school psychologists do engage in consultation activities (Curtis, Walker, Hunley, & Baker, 1999). However, many practitioners identify limitations to implementing consultation due to time constraints and lack of consultee commitment (Gresham & Kendell, 1987). Both individual consultant/consultee and system issues must be addressed to deal with those constraints.

Overall, problem-solving consultation is a rapidly growing area with increasing empirical support. However, future studies must utilize more sophisticated designs and measurement strategies to evaluate variables in consultation. Careful scrutiny of consultation will impact its future use as an alternative to traditional assessment and intervention practices in educational settings and may result in an increased emphasis on the development of formalized training in school psychology programs. In turn, these developments would contribute to the practice of school psychology and positively impact the children, teachers, and parents receiving psychological and educational services.

APPENDIX: BEHAVIOR INTERVENTION RATING SCALE

You have just read about a child with a classroom problem and a description of an intervention for improving the problem. Please evaluate the intervention by circling the number which best describes *your* agreement or disagreement with each statement. You *must* answer each question.

		Strongly Disagree	Disagree	Slightly Disagree	Agree	Strongly Agree
1.	This would be an acceptable intervention for the child's problem behavior.	1	2	3	4	5
2.	Most teachers would find this intervention appropriate for behavior problems in addition to the one described.	1	2	3	4	5
3.	The intervention should prove effective in changing the child's problem behavior.	1	2	3	4	5
4.	I would suggest the use of this intervention to other teachers.	1	2	3	4	5
5.	The child's behavior problem is severe enough to warrant use of this intervention.	1	2	3	4	5
6.	Most teachers would find this intervention suitable for the behavior problem described.	1	2	3	4	5
7.	I would be willing to use this intervention in the classroom setting.	1	2	3	4	5
8.	The intervention would *not* result in negative side-effects for the child.	1	2	3	4	5
9.	The intervention would be appropriate for a variety of children.	1	2	3	4	5
10.	The intervention is consistent with those I have used in classroom settings.	1	2	3	4	5
11.	The intervention was a fair way to handle the child's problem behavior.	1	2	3	4	5
12.	The intervention is reasonable for the behavior problem described.	1	2	3	4	5
13.	I liked the procedures used in the intervention.	1	2	3	4	5
14.	The intervention was a good way to handle this child's behavior problem.	1	2	3	4	5
15.	Overall, the intervention would be beneficial for the child.	1	2	3	4	5
16.	The intervention would quickly improve the child's behavior.	1	2	3	4	5

		Strongly Disagree	Disagree	Slightly Disagree	Agree	Strongly Agree
17.	The intervention would produce a lasting improvement in the child's behavior.	1	2	3	4	5
18.	The intervention would improve the child's behavior to the point that it would not noticeably deviate from other classmates' behavior.	1	2	3	4	5
19.	Soon after using the intervention, the teacher would notice a positive change in the problem behavior.	1	2	3	4	5
20.	The child's behavior will remain at an improved level even after the intervention is discontinued.	1	2	3	4	5
21.	Using the intervention should not only improve the child's behavior in the classroom, but also in other settings (e.g., other classrooms, home).	1	2	3	4	5
22.	When comparing this child with a well-behaved peer before and after use of the intervention, the child's and the peer's behavior would be more alike after using the intervention.	1	2	3	4	5
23.	The intervention should produce enough improvement in the child's behavior so the behavior no longer is a problem in the classroom.	1	2	3	4	5
24.	Other behaviors related to the problem behavior also are likely to be improved by the intervention.	1	2	3	4	5

The Children's Intervention Rating Profile

		I agree				I do not agree
1.	The method used to deal with the behavior problem was fair.	+	+	+	+	+
2.	This child's teacher was too harsh on him	+	+	+	+	+
3.	The method used to deal with the behavior may cause problems with this child's friends.	+	+	+	+	+
4.	There are better ways to handle this child's problem than the one described here.	+	+	+	+	+
5.	The method used by this teacher would be a good one to use with other children.	+	+	+	+	+
6.	I like the method used for this child's behavior problem	+	+	+	+	+
7.	I think that the method used for this problem would help this child do better in school	+	+	+	+	+

ANNOTATED BIBLIOGRAPHY

Bergan, J. R., & Kratochwill, T. R. (1990). *Behavioral consultation in applied settings.* New York: Plenum.

The authors provide an extensive overview of behavioral consultation research and practice. The text provides detailed information for researchers and practitioners in the conduct of behavioral consultation. The text is accompanied by a companion self-instructional guide (see Kratochwill & Bergan, 1990).

Hayes, S. C., Barlow, D. H., & Nelson-Gray, R. O. (1999). *The scientist-practitioner: Research and accountability in the age of managed care.* Boston: Allyn & Bacon.

The authors outline specific assessment and measurement strategies that can be used in consultation. The text is especially useful in outlining assessment strategies and case study techniques that can be helpful during the intervention implementation and intervention monitoring phase of consultation.

Morris, R. J., & Kratochwill, T. R. (Eds.) (1998). *The practice of child therapy* (3rd ed.). Boston: Allyn & Bacon.

The editors provide an overview of various intervention approaches that is organized by the major childhood disorders. Although many of the interventions described are used in a direct therapy application, numerous approaches can be used by consultation mediators, especially with training.

Stoiber, K. C., & Kratochwill, T. R. (Eds.). (1998). *Handbook of group interventions for children and families.* Boston: Allyn & Bacon.

The editors provide an overview of various intervention approaches that can be implemented in group formats. The text is organized by topical areas, and interventions can be implemented by both consultants and mediators.

40 Best Practices in Instructional Consultation

Sylvia Rosenfield
University of Maryland

OVERVIEW

Instructional consultation is a stage-based problem-solving process that brings the school psychologist, as a consultant, and the teacher, as consultee, together to focus on school-based academic and behavioral concerns. Teachers bring concerns about students to the instructional consultant, as is typically done in other forms of school consultation. One of the unique aspects of instructional consultation, however, is the focus on academic concerns within an ecological framework. Although behavioral, as well as instructional, concerns are brought to the instructional consultant, appropriate academic progress is a pervasive consideration because of its centrality to the goals of schooling.

In this chapter, basic considerations will involve discussion of the essential assumptions underlying the practice of instructional consultation and of the training required. Next, best practices in conducting the instructional consultation process will be delineated. The following elements will be presented: the collaborative relationship and communication skills upon which instructional consultation is built, the stages of the process, a form useful in structuring the process, and the incorporation of the process into a service delivery model called instructional consultation teams (IC-Teams).

BASIC CONSIDERATIONS

In *School Psychology: A Blueprint for Training and Practice II*, Ysseldyke et al. (1997) recommend that school psychology practice should include the domains of interpersonal communication, collaboration and consultation, effective instruction, and development of cognitive/academic skills. These domains are blended in instructional consultation. Bergan and Schnaps (1983) described instructional consultation as behavioral consultation in situations designed to "modify teacher behavior to enhance the learning of all students in a class" (p. 105). Rosenfield (1987) extended the concept, developing underlying assumptions and incorporating content and skills into a stage-based problem solving process. The IC-Teams (Rosenfield & Gravois, 1996) is a delivery system to support implementation of instructional consultation. Because transformation to an indirect service delivery model requires systems change in most settings, the IC-Team model also incorporates knowledge about and skills in facilitating organizational change.

Underlying Assumptions

The perspective of the school psychologist in the role of instructional consultant is as critical to the process as are the strategies and techniques. Consultation is not a passive process. As White, Summerlin, Loos, and Epstein (1992) explicitly state, the "facts of a particular case are but a reflection of the values and prejudices of those persons describing that situation" (p. 350). The ecological perspective of instructional consultation differs significantly from that of the traditional medical model, requiring a collaborative focus "on the interactions between the student's entry level skills, the design of instruction, and the actual task the student is asked to perform rather than on a search for an internal deficit" in the student (Rosenfield, 1995, p. 320).

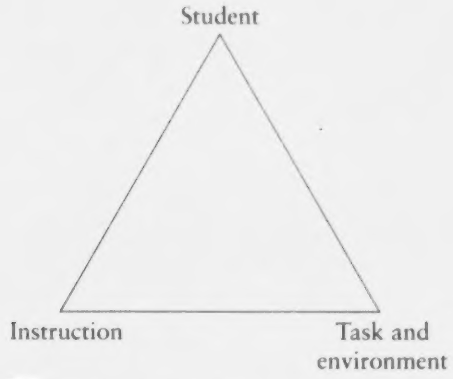
THE INSTRUCTIONAL TRIANGLE

Given that the context of schooling impacts on the individual learner and his or her adaptations to this environment, teacher concerns about students are viewed from the perspective of an instructional triangle (see Figure 1), consisting of the student, the task, and the instruction/management strategies. The learner is one component of the instructional system. The focus on the learner, however, is on alterable learner variables (Bloom, 1976), such as current behavior and academic entry level skills, rather than stable traits, such as intelligence.

Teaching objectives are operationalized by teachers into specific tasks for students, and these tasks comprise the second point of the triangle. Teacher expectations are generally based on successful completion of these tasks, and teachers evaluate student progress based on student performance of these tasks. However, it is not the task itself but the relationship, or match, between the tasks and the learner's skill level that is assessed in instructional consultation. A problem occurs when there is a gap between the expected performance level of the task and the student's skill level.

The instructional and/or management strategies used by those teaching the student are examined as the third point of the triangle. The importance of instructional design features on student learner outcomes has been confirmed in the empirical literature, most recently summarized by Kavale and Forness (1999). The instructional psychology literature (see, e.g., Ysseldyke & Christenson, 1993), as translated into instructional techniques acceptable in the consultee's classroom practice, are essential components of the instructional consultant's knowledge base.

Figure 1. The instructional triangle



From Gravois, Rosenfield, & Gickling, 1999.

THE LEARNING COMMUNITY

In addition to the assumptions inherent in the instructional triangle, the instructional consultant is committed to the assumption that creating communities for educators is essential to creating learning communities for students. The research literature (see, e.g., Fullan & Hargreaves, 1991; Rosenholtz, 1989) confirms that collaboration and consultation that support educators' reflective activities and professional development also are basic to the well being of their students. A teacher's referral is not viewed as a request to determine a student's disorder or as a prelude to special education placement. Rather, instructional consultants interpret a referral for consultation and collaboration as a normal function within a school community when either learning or behavior, or both, of a student or students are not progressing at an acceptable pace. This assumption is in contrast to how many schools operate, in which teacher isolation and individualism is the norm even when problems occur. Studies confirm that schools in which professional reflection and teacher collaboration (Fullan & Hargreaves, 1991) are embedded in the culture produce more effective academic outcomes.

DATA-BASED DECISION MAKING

Best practice in problem solving is data-driven. Gathering systematic classroom data for instructional decision making, which may not typically be part of the usual professional culture of teachers or the norm of most schools, is a required component of instructional consultation. School psychologists can play an important role in providing support and leadership in this area. Evaluation and accountability are expected (e.g., Stoner & Green, 1992) in all aspects of instructional consultation, even when using empirically supported interventions. Because it is not possible to determine the effectiveness of a specific intervention in any given case, baseline comparison and intervention data are necessary to determine the effectiveness of the intervention and/or the need to change the intervention design if there is a lack of progress.

Training in Instructional Consultation

Basic skills in school-based consultation are essential for school psychologists working as instructional consultants. These include ability to establish a consultation relationship and to conduct the stages of the consultation process. There is overlap in the skills of behavioral consultants, including defining concerns in observable and measurable terms, setting goals, collecting baseline and intervention stage data, graphing and charting, and data-based decision making about outcomes. For many classroom-based problems, behavioral interventions, either alone or in combination with instructional and management techniques, result in positive outcomes.

However, an additional set of attitudes, knowledge, and skills is required for effective instructional consultation. First, ecological assumptions must be a comfortable fit. School psychologists who view teacher concerns as a call to identify student disabilities can be resistant to assessing the instructional and management environment surrounding the teacher referral in the same depth as the student characteristics. Second, sound knowledge and skill in Curriculum-Based Assessment (CBA) techniques (e.g., Gickling & Gravois, this volume), and instructional design and classroom management interventions (see, e.g., Ysseldyke & Christenson, 1993), are essential. One of the professional development goals of instructional consultants is to build a repertoire of effective research based interventions in these domains.

BEST PRACTICES IN INSTRUCTIONAL CONSULTATION

There are several distinguishing characteristics of instructional consultation, although its stages are similar to behavioral consultation. In instructional consultation, special emphasis is given to relationship building, communication skills, and academic concerns.

Consultation Relationship

Collaborative consultation is defined as an "interchange between two or more professional colleagues, in a nonhierarchical relationship, working together to resolve a problem" (Rosenfield, 1987, p. 21). To facilitate problem solving, it is critical to establish a working relationship, one that allows the individuals involved to keep the problem-solving process going in spite of potential differences in interests, values, and perceptions (Fisher & Brown, 1988). Issues around the cost of seeking help and the processes for influencing consultees have been described in the literature and are applicable to the instructional consultation model as well (see, e.g., Rosenfield, 1987).

While both parties are responsible for the problem-solving outcomes, the consultant has the additional obligation to monitor and negotiate the quality of the relationship; thus, a discussion of the relationship is important early in the process. The capacity to build a working relationship is especially important in instructional consultation because of the focus on the whole instructional system rather than on finding and remediating a student's disability. Without a good working relationship, the participants' ability to work on curricular, instructional, and management issues would be severely diminished.

The school psychologist must also be perceived as authentic and trustworthy, developing these characteristics through interpersonal skills and effective communication strategies. It is often difficult for consultants "to balance their own perspective on the case with norms of good manners, desires to avoid any hint of disagreement or selfishness, and wishes to avoid confronting a colleague" (Rosenfield & Gravois, 1996, p. 25). These difficulties are compounded when teachers are asked to examine their instructional methods or to make changes in daily routines.

Communication Skills

Consultation is viewed, at its core, as a linguistic event, in which the problem and solution are constructed through dialogue (Rosenfield, 1999; White et al., 1992). The consultant functions as the architect of the dialogue, creating space for and facilitating the consultation conversation. Social psychologists inform us that speakers modify their descriptions of situations to take into account their perceptions about what their listeners want to hear, and the process of talking about a problem generates a sense of objectivity about it (Higgins, 1999). Thus, the conversation about the consultee's concerns must be carefully constructed. Consultants often are unaware how much their language affects the process. Structured reflection using tapes of their own consultation interviews is a powerful tool for alerting consultants to their use of language in the consultation sessions and its impact on the process.

Communication skills are central to establishing a collaborative working relationship and constructing the problem in a form that school staff find meaningful and resolvable within their own professional role. Medical model diagnosis can result in a teacher's believing that only a specialist can address the disorder. In contrast, a problem defined in terms of classroom learning objectives and behavior is viewed by teachers as functionally related to their role. Thus, specific behaviors and skills are the focus of the consultation sessions, since there is evidence that the focus of the problem identification affects the teacher's beliefs about whether the problem can be resolved at the classroom level. According to Tombari and Bergan (1978), teachers felt more empowered to resolve a problem when they were asked to respond to questions about behavior rather than more medical model cues.

In developing a collaborative relationship, question asking is downplayed, because of its expert orientation, and alternatives to questions are emphasized (Rosenfield, 1987). Clarity of communication is essential because generalities or ambiguous phrases are common in problem identification interviews. For example, a teacher may describe a student as having attention problems. Through clarifying comments, such as, "an example of that would help," the teacher is able to describe the behavior that led to the inference about the student's problem. Helping teachers to move down the "ladder of inference" (Argyris, 1990) from labels to behavior is a key aspect of communication. Paraphrasing of the consultee's statements is also helpful as a check that the consultant's understanding of the consultee's message is congruent with what was intended and affords an opportunity to correct the received message. Paraphrasing also provides the teacher with the chance to reflect on the message through hearing it again, a rare opportunity given how little time is provided on a regular basis in the schools for such reflection.

It is essential for instructional consultants to be aware of the language that they use in the consultation process. In educating instructional consultants, supervisors consistently find that new consultants are unaware of what they have actually said (as different from what they intended to say) and of the impact of their language on the consultee. All consultants should have multiple opportunities during their training, and periodically thereafter, to tape some of their consultation sessions so that they can reflect on and improve their use of language and communication skills.

Problem-Solving Stages

The stages of problem solving in instructional consultation are entry and contracting, problem identification and analysis, intervention planning, intervention implementation, and resolution/termination. The stages serve as a scaffold for the problem-solving process, and each stage has tasks that need to be accomplished before the next stage can be addressed. Failure to complete the tasks required at each stage can diminish the effectiveness of the process. While the stages are described in a linear fashion (see Figure 2), it is not unusual to return to an earlier stage if the situation changes or if it is recognized that there has been a breakdown in the process. For example, if it becomes apparent that the teacher's expectations about the process are not being met, the consultant and consultee should return to the contracting stage and renegotiate the consultation contract.

ENTRY AND CONTRACTING

Introduction to consultation takes place at two levels, the school and the individual teacher. *Entry* refers to the process of introducing instructional consultation to administrators, staff, and parents in the school as a major component of the school psychologist's service delivery model. Practitioners have accomplished this through presentations at staff meetings and through written materials, including brochures and newsletters for teachers and parents. As part of entry, information is provided about the referral procedure through which staff accesses the consultation services. Referring a concern should be easy for the consultee, usually consisting of a one-page request for consultation with an indication of the teacher's available time periods. It is not considered a student referral so much as a request for support or consultation about a stu-

dent or set of students in the teacher's classroom. The first consultation session should be scheduled soon after the referral is made. It should be noted that to implement the IC-Team model, systems level entry is also advised (Rosenfield & Gravois, 1996).

Introduction of instructional consultation at the school level does not absolve the school psychologist from the requirement of *contracting* with the individual teacher consultee. Contracting provides the consultee with the ground rules that govern the consultation relationship and problem-solving process. It concludes with an explicit decision about whether or not to engage in the problem-solving process. Contracting can be considered a method to obtain informed consent to proceed.

The business of contracting involves the following:

1. Informing the consultee about the stages of the problem solving process
2. Explaining the instructional triangle (with its focus on alterable student variables, instructional methods, and tasks in the classroom)
3. Clarifying the collaborative nature of the relationship
4. Discussing time involvement
5. Explaining data collection
6. Discussing the limits of confidentiality and the non-evaluative nature of the process (before engaging in consultation, it is critical for the consultant to clarify the school/school district policy on student and teacher confidentiality, so that the teacher can be accurately informed)
7. Concluding with a joint decision to move forward, including scheduling time and place, or to discontinue meeting

Decisions about the role of parents in instructional consultation must be made at the school or district level. Some consultants and schools view consultation as providing an opportunity for teachers to obtain support for a problem with some aspect of the instructional triangle in their classroom; and others insist that any discussion about a student, even regarding classroom instructional modifications, must be predicated on parental notification and/or permission. In schools in which IC has been implemented, teachers report being able to engage in more productive dialogue with parents after engaging in instructional consultation. Rather than focus on the student's problems, they can base their discussions with parents on more specific academic concerns and behaviors, have useful data to share, have set specific goals, and may have introduced instructional modifications matched to the student's skill level. At all times, the culture of the school with respect to parent involvement needs to be clear to the consultant and respected.

PROBLEM IDENTIFICATION AND ANALYSIS

After there is a joint decision to engage in the problem-solving process, the stage of *problem identification and analysis* begins. The instructional consultant does not assume that the initial description of the problem is an adequate representation, but rather that the participants will co-construct the problem through their dialogue and data collection. The outcome of this stage is problem setting, framing problems in terms of current versus desired performance. The concern should be meaningful to the participants and respectful of their perspectives, but amenable to allowing change to occur in components of the instructional triangle.

Care is taken in the language used in this stage to avoid diagnostic and clinical jargon, and to focus first on the presence or absence of behaviors that led the teacher to decide that a referral was needed. Teachers often attune their concerns to their listeners, and school psychologists, for example, are often more prone to be told that the student may have an attention deficit disorder than to hear about a problem in learning phonics, although behaviors related to both may be present. Reframing the initial, often global, concern to specific behavior(s) also can have the effect of leading teachers to feel more empowered to resolve the problem, as suggested above.

The business of this stage can take several sessions, depending in part upon the information that the consultee brings to each session. The goal is to:

1. Identify the teacher's concerns in observable and measurable terms, and define it in terms of a "gap" between current and expected performance.

2. Select a data collection method and establish a baseline.

3. Identify the antecedent and consequent conditions in the context in which the behavior or academic performance problem occurs; that is, a functional analysis is appropriate whether the concern is a classroom behavior or an academic performance problem (Daly, Witt, Martens, & Dool, 1997).

4. Establish short- and long-term goals for the student.

Problem identification is accomplished through the dialogue conducted during the consultation sessions, and through carefully designed assessments, usually involving CBA and behavioral observation techniques. The goal of assessment is to identify whether there is a gap between the student's current and expected performance, as defined by the teacher, and determine if that gap is significant. Thus, defining a gap requires that the referral source have clear expectations for the student and can identify the student's skill level with respect to those expectations. Assessment strategies are designed to supply information about the student's entry-level skills or behaviors, the task, and the instructional/management strategies in use.

A critical feature of instructional consultation is the requirement that an instructional mismatch be ruled out, even when the teacher's presenting concern is behavior. Thus, for example, if the teacher reports that the student is not completing the work or is constantly interfering with the work of other students, the first hypothesis to be tested is the appropriateness of the tasks assigned in relation to the student's entry skills. The requirement for an academic assessment is predicated on the assumption that students who are working at frustration level in the classroom instructional setting can be prone to behave inappropriately as well.

The teacher and consultant establish whether the student is given tasks that match his/her entry-level skills through the use of CBA strategies. CBA is defined as "a system for determining the instructional needs of a student based upon the student's ongoing performance within existing course content in order to deliver instruction as effectively and efficiently as possible" (Gickling, Shane, & Croskery, 1989, pp. 344–345). Surprisingly, "most teachers either do not take the time or do not know how to make good use of assessment in presenting instruction, in evaluating it, and in making it more effective and meaningful" (Stiggins & Conklin, 1992, p. 148). Instructional assessment is thus an essential tool within the problem identification stage. CBA addresses five basic questions: What does the student know? What can the student do? What does the student think? How does the student approach what he or she is unsure of? What can the teacher do next? (For additional information on assessment and intervention techniques growing out of CBA, see Gickling & Gravois, this volume).

Behavioral observation techniques in the classroom or school setting are routinely used by school psychologists, but instructional consultation also requires that relationship issues are considered in the planning of observations and in providing feedback about the data. It is important for teacher and consultant to reflect together on the specific purpose of the observation with regard to the teacher's concern, and to develop strategies that minimize bias and facilitate the decision-making process. The consultant needs to involve the consultee in interpreting the data. Most school psychologists are willing to conduct classroom observations when a referral is made, but it is often valuable to have the teacher do the observation. Simple observation techniques that can be maintained by the teacher during the intervention stage are particularly helpful in facilitating data collection through the intervention stage of consultation, and in helping the teacher in gaining a more objective perspective on the concern.

Data from the assessment are compiled in a graph or chart format. A baseline on the behavior/academic skill of concern is established. While technical perfection in data collection is not always the case, over time teachers and consultants seem to develop a healthy respect for the process, and recognize that the graphing and charting of data are essential components.

INTERVENTION PLANNING

Intervention planning is facilitated by successful completion of the problem-identification stage. Teachers are often able to develop interventions when they have a clear definition of the problem and data to support the picture that has been constructed. Labeling a student's reading problem as a learning disability often is interpreted by the teacher to mean that the student requires the services of a special education teacher. On the other hand, recognizing that the student's reading problem is the result of insufficient knowledge of phonics can enable the teacher to accept empirically supported strategies, tailored to fit the classroom context, to teach phonics skills. Failure to complete independent seat work can be labeled an attention disorder. Again, an alternative hypothesis can be developed if assessment reveals that the work is not at instructional level. Then the teacher can develop tasks to better match the student's skills.

This stage is completed only when the details of the intervention are described and the implementation of the intervention is seen as realistic and reasonable by those responsible for conducting it. The planning requires that the following questions be answered:

1. What is the description of the strategy?
2. When and how often will it be implemented?
3. By whom will the intervention be implemented?
4. What materials are required and are they currently available? (If not, how will they be obtained?)
5. What data collection methods will be used to evaluate progress toward the student's goals?
6. When will progress be monitored?

To the extent possible, intervention selection is based on utilizing effective, research-based, instructional, and classroom management strategies. However, research evidence does not guarantee effectiveness in any given case, and many strategies need to be tailored to the demand of a particular classroom setting or student situation. For example, in developing behavioral interventions, the technique of contracting is highly effective; but an effective contract may not be constructed on the first attempt. Building a student's sight word vocabulary may require modification of the number of new words introduced per lesson and the type of reinforcement used. Instructional consultants share with consultees the understanding that the first intervention plan may need to be modified and that decisions about modifications will be based on the data gathered to monitor progress toward goals.

INTERVENTION IMPLEMENTATION

The feasibility and effectiveness of an intervention are put to the test in the *intervention implementation* stage. The beneficial effect of creating a collaborative working relationship on treatment implementation has been documented (see, e.g., Vaughn, Hughes, Schumm, & Klingner, 1998). Collaboration during this stage is an asset in resolving the inevitable practical problems that arise during implementation, coping with treatment integrity issues, and supporting data collection on the effectiveness of the intervention. Consultants should be prepared for problems in these areas rather than view them as evidence of teacher resistance. While sessions are typically less frequent during this stage, meetings to evaluate progress and treatment integrity should be scheduled at regular intervals.

RESOLUTION/TERMINATION

Formal closure of the problem solving process and the working relationship (at least about this particular case) is the final stage. Whether or not the problem has been resolved to the satisfaction of all parties, accountability requires a *resolution/termination* stage, where the decision to continue or terminate is made. If the goals have been achieved and the problem is resolved to the partners' satisfaction, then there is the opportunity to celebrate the achievement. The procedure for re-accessing the consultant should be clarified should new concerns emerge.

If there is not progress toward goals when the data are reviewed, then it may be necessary to recycle back through the stages. For example, a more clearly defined behavior or additional data collection may be needed. Alternatively, a decision to access other resources can be made, including a support team in the building, or involvement of, other staff (either internal to the school or in the community) or family members. Special education referral may be considered if that is the most direct way to access needed resources.

If the teacher decides not to continue in the relationship, then formal termination of the process should occur. Consultation relationships can fade away through the press of time, personal concerns (such as an illness in the teacher's family), unwillingness to confront relationship issues, or perceived or real lack of progress in resolving the referral concern(s). It is important to explicitly address the reason for the teacher's withdrawal, and to terminate the process while leaving the door open for future opportunities to consult on the current or other concerns.

Documentation is required for accountability in all situations. The consultee should be a partner in constructing and completing the records. Rather than a formal report written by the consultant, documentation for the teacher should be a brief summary of the concern, relevant assessment data, a description of the interventions implemented, and the results. A summary form with instructional and management recommendations can be prepared for the student's next teacher (see Figure 3 for an example of such a form). Records should be maintained in the event of future concerns about a particular student, with culling of outdated records when appropriate. For consultant accountability, it is important to examine how many consultee concerns are successfully addressed during the school year.

Student Documentation Form

The Student Documentation Form (SDF) is designed to structure and provide accountability for the instructional consultation process. This four-page folder, printed on heavy paper stock, is useful for moving through the stages in a systematic manner. The cover page (see Figure 4) enables the consultant to structure the problem identification stage by

1. Eliciting the concerns in general terms
2. Helping the consultee to prioritize the concerns
3. Requiring an examination of instructional match between the student's skills and the classroom tasks
4. Setting short and long-term goals

Inside the SDF there are two identical facing pages (see Figure 5) that provide a place to

1. Identify the behavior
2. Chart and graph baseline and intervention data
3. Assure that the major intervention design components have been addressed

The back cover (see Figure 6) provides a log form for sessions. After an evaluation of an earlier version of the SDF (Moniodis, 1996), the current format was developed, based on these results, in collaboration with psychologists, teachers, and administrators implementing IC-Teams.

IC-Teams

The instructional consultation process has been embedded in a delivery system called IC-Teams. IC-Teams (Rosenfield & Gravois, 1996) is a structured school-wide problem-solving team model that is based on the assumptions and process of instructional consultation. Individual team members are trained as instructional consultants and work with teachers in the school building. In addition, IC-Teams, as a program model, includes specification of the functions of the team, a process by which school staff can access the team as a resource and procedures for accountability.

There is a process described for implementation of the team model, based on the school change literature, and described in Rosenfield and Gravois (1996). A training program for both team members and team facilitators has been designed, and there is an evaluation process for the team that includes a level of implementation measure, the IC-Team LOI-Revised (Fudell, Gravois, & Rosenfield in Rosenfield & Gravois, 1996, Appendix A). Most of the IC-Teams currently operating have school psychologists as their facilitators.

An essential component of IC-Teams is the emphasis on data collection from the level of individual cases to program evaluations. Program evaluation data have been collected on outcome variables, including student goal attainment, reading achievement outcomes, special education referrals and placements, and time use patterns. Process variables have also been examined, including level of implementation, effectiveness of training, and school staff satisfaction. For each school system in which IC-Teams have been implemented, yearly reports are provided to the school district on a selected number of these variables, using charts, graphs, and narrative summaries. These reports have been used within schools to plan training for teams and by the district administrators and boards of education to determine funding and expansion of the teams. (A bibliography and set of sample reports are available from the author.)

IC-Teams are generally implemented in elementary schools, although a similar model has been extended to middle school settings as well . At the middle school, an IC-Team consultant typically works on a regular basis with grade-level teams to implement the problem-solving process, bringing the assumptions and techniques of instructional consultation to the teachers as they discuss student issues.

SUMMARY

Instructional consultation is a stage-based problem-solving model that connects the collaborative consultation process with the knowledge base in academic assessment and classroom instruction, particularly as it is applied to concerns of teachers about student learning and behavior. The underlying assumptions

Figure 6. Student documentation form, log form

Date	Summary of Meetings	Follow-up Activities	Next Meeting Date and Time

are ecological in nature and focus on the instructional triangle of alterable student variables, instructional tasks, and instructional design. Each of these variables are assessed in relation to each other to determine if there is a gap between the student's current and expected performance as well as a functional analysis of the cause.

School psychologists functioning as instructional consultants have basic school consultation skills. In addition, they must be comfortable with the ecological assumptions described above. Although similar to behavioral consultants in their training, the instructional consultant must also be knowledgeable about academic assessment and the domains of instruction and classroom management.

The instructional consultation process relies on the school psychologist's ability to build a working relationship with the teacher through interpersonal skills and good communication strategies. The consultation process involves specific stages of problem solving, each with its own tasks. The stages include: entry and contracting, problem identification, intervention planning, intervention implementation, and resolution/termination. When the concern has not been resolved, the stages can be recycled or additional resources accessed.

Data-based decision making is central to instructional consultation. To this end, documentation of the process is critical for accountability. The SDF, developed in collaboration with school personnel, provides a format for this process, and also helps to structure the problem-solving stages.

In recognition that schools as organizations often require greater structure for service delivery, the IC-Team model, in which the instructional consultation process is embedded, was developed. School psychologists have become valued facilitators of these teams, but facilitation requires skills in teaming, evaluation, and implementation of school change.

Instructional consultation brings school psychologists into contact with the daily classroom concerns of teachers. It is a collaborative process that provides services that affect teacher behavior and student progress.

ANNOTATED BIBLIOGRAPHY

Gickling, E., & Gravois, T. A. (this volume). Best practices in curriculum-based assessment.

An essential tool for instructional consultants is CBA. The major type of CBA used by instructional consultants is described in this chapter, and the basic assumptions and strategies are presented.

Rosenfield, S. A. (1987). *Instructional consultation.* Hillsdale, NJ: Erlbaum.

The text provides the foundation for instructional consultation. It introduces readers to an extensive, step-by-step description of the instructional consultation process, providing case material, resources, and materials available to foster the consultation process.

Rosenfield, S. A., & Gravois, T. A. (1996). *Instructional consultation teams: Collaborating for change.* New York: Guilford.

This book covers both the content and the process of creating consultation-based services for students, staff, and school communities through implementation of IC-Teams. It describes the instructional consultation model, followed by a discussion of the role of the change facilitator and the stages of change. Individual chapters are devoted to initiating, training, implementing, and institutionalizing IC-Teams.

Ysseldyke, J., & Christenson, S. (1993). *The instructional environment system (TIES)-II.* Longmont, CO: Sopris West.

Instructional consultants must have a solid understanding of effective instructional design. The TIES presents an overview of the knowledge base in instruction and management, and presents some tools to evaluate a student's instructional setting.

41 Best Practices in School Consultation

Joseph E. Zins
University of Cincinnati
William P. Erchul
North Carolina State University

OVERVIEW

Consultation has become one of the primary job functions of many school psychologists (Reschly & Wilson, 1995). This trend in practice is supported by a mounting body of empirical evidence demonstrating the efficacy of consultative services (e.g., Sheridan, Welch, & Orme, 1996), although there continues to be great need for further research on all aspects of the process.

Our goal in this chapter is a very practical one. We intend to present essential information about what is needed to be an effective school consultant. Although considerable theoretical and empirical literature is cited, our intent is not to provide a thorough review of it, because that information is available elsewhere (e.g., Erchul & Martens, 1997; Zins, Kratochwill, & Elliott, 1993). Further, we assume that most readers already have at least a basic-level understanding of consultation. For those who wish more detail than can be provided in this brief chapter, several recommended references are listed in the annotated bibliography.

The chapter begins with a presentation of our conceptualization of consultation along with the prerequisite competencies and assumptions underlying practice. Practical guidelines for best practices in consultation are discussed, including a description of consultative problem-solving steps. The chapter concludes with a review of individual and organizational factors that may exert influence on the consultation process.

BASIC CONSIDERATIONS

Several approaches to consultation most frequently employed in the schools have been described in the literature: the behavioral, mental health, and organizational. Although universally accepted definitions for these approaches do not exist, and the models were not specifically developed for practice in the schools, they have a number of elements in common. For instance, all stress the use of problem solving as the mechanism through which consultative interventions are developed, focus on work-related problems, and view participation in the process as voluntary. However, they differ in aspects such as the roles and relationships of consultants and consultees, the focus of consultative interventions, and the organizational level at which they are implemented. Despite the differences and lack of agreement in definition, the approaches are more similar than different, and consensus is emerging regarding key elements of the process (Zins et al., 1993).

The approach to consultation described in this chapter borrows heavily from a variety of models, but theoretically is most closely aligned with the ecobehavioral approach, which combines the behavioral and ecological/systems paradigms (Gutkin, 1993). It emphasizes the application of behavioral technology, and utilization of the broad-based ecological/systems perspective. We have extracted the most salient aspects of a number of prior works, added some new ideas, and synthesized this information into a coherent framework specific to practice in the schools.

Schools are different from other settings such as hospitals, correctional facilities, or business organizations, and because context is such an important aspect of consultation, it is desirable to limit the focus to school consultation. Such an approach also provides the latitude to review briefly the various types of consultation that occur within schools, including consultation with individual teachers and parents, with groups of consultees, and system-wide consultation directed toward changing entire educational organizations.

Definition of School Consultation

In this chapter, school consultation is defined as *a method of providing preventively oriented psychological and educational services in which consultants and consultees form cooperative partnerships and engage in a reciprocal, systematic problem-solving process guided by ecobehavioral principles. The goal is to enhance and empower consultee systems, thereby promoting students' well-being and performance.* A brief explanation of the essential components and underlying assumptions of this definition follows. Ideas from many sources form the basis of this discussion, and it is difficult to attribute original responsibility for many of the concepts. As Gutkin and Curtis (1999) noted, these ideas have now been so widely discussed that they are now part of the basic assumptions typically made about consultation (although not all have been validated empirically).

PREVENTIVE-ORIENTATION

Consultation has a dual focus. Consultation provides a mechanism through which the presenting problem is remediated, and, secondarily, it attempts to increase consultees' skills and alter environmental variables and setting events that elicit and maintain problematic behaviors. These procedures are intended to prevent problems from becoming more severe and to keep additional ones from arising.

The first goal is met by developing specific, empirically based interventions to deal with the presenting problem. The second is accomplished in a less direct manner by (a) ensuring that the consultant's expertise is readily available to the consultee system through encouragement of frequent interactions between consultants and consultees to facilitate the prevention and early identification of problem behaviors; (b) improving consultees' skills and knowledge so they can more effectively address similar problems in the future; (c) maintaining a systems perspective so that the broad array of conditions that might contribute to problem development, maintenance, and resolution are considered and can be addressed; and (d) developing and implementing primary and secondary prevention programs. In most cases, it is necessary for consultees to solve several problem situations successfully with the consultant's support before the consultees apply those procedures independently, as the literature suggests that training to a single exemplar is ineffective as a means of promoting generalization (Stokes & Baer, 1977). Even when consultation is applied in a clearly rehabilitative fashion, a primary intent is to minimize the possibility that more serious problems will arise. In practice, this preventive goal is not accomplished as often or as easily as the first; nevertheless, it should be pursued to enhance the overall value of the consultation process (Zins, 1995).

The increasingly preventive focus of consultation gradually is shifting the focus from individual children to entire systems; that is, classrooms, schools, school districts, the larger community, and even relevant state and federal policies, regulations, and legislation (Swift & Cooper, 1986). Practitioners, who are often frustrated by the limitations of focusing interventions on individual children, now are recognizing the potential efficacy and long-term benefits of wide-scale interventions (see Perry et al., 1996, for illustration).

METHOD TO PROVIDE SERVICES

Consultation is one means by which psychological and educational services are provided, or what Miller (1969) might describe as another way of "giving psychology away" to non-psychologists. Indeed, consultation is the foundation or overarching framework from which all other services are delivered and around which all other services are organized. The goal is to help clients (usually students) and the consultee system. Students are assisted indirectly through the process, in contrast to the direct method of providing service traditionally associated with psychoeducational assessment or counseling, recognizing that there is a need for both types of services, and that even with a direct service such as individual crisis intervention, consultation with teachers and/or parents usually is provided. Further, techniques such as modeling, direct instruction, and behavioral rehearsal, which involve direct interactions with clients (children) and/or consultees, may also be appropriate to ensure that consultees learn the skills. As noted later, it is essential for consultants to remain available for follow-up assistance and support for interventions that are developed. The important point is to assist in resolving the problem rather than rigidly adhering to certain roles. For example, direct training of consultees in problem solving skills (Zins & Ponti, 1996), or having consultants model particular behaviors (Watson & Robinson, 1996), have been demonstrated to enhance effectiveness and improve integrity.

COOPERATIVE PARTNERSHIP

Consultants and consultees work together to solve problems, and it is highly desirable for them to do so within a relationship that emphasizes trust, openness, and a sharing of responsibilities and expertise. We term this relationship a "cooperative partnership." *Cooperative* implies that (a) participants work jointly on as equal a basis as possible (realizing that their levels of need are unequal and their areas of expertise are often divergent), and (b) they have different contributions to make and varying responsibilities to uphold to maximize consultation effectiveness. *Partnership* implies that these responsibilities are clearly specified and mutually agreed-upon to facilitate progress toward common goals.

In terms of specific responsibilities, consultees must provide contextual, ecological information to help define problems and develop interventions. They also must assist in determining what interventions can be implemented in their setting and within their repertoire of skills. In addition, all participants have responsibility for defining and analyzing problems, for establishing and maintaining the cooperative partnership, and for conducting follow-up activities.

Although consultants and consultees both contribute to problem solving, consultants structure and guide the overall process, while consultees supply much of the content of the discussion. Consultant attempts to direct the course of consultation interviews have been linked to a variety of positive outcomes (e.g., Fuchs, Fuchs, Bahr, Fernstrom, & Stecker, 1990), but consultee attempts to control the direction of interviews generally have been associated with more negative outcomes (e.g., Erchul & Chewning, 1990). However, because consultees (a) retain responsibility for the client, (b) can best judge treatment acceptability, and (c) usually implement most interventions and thus can ensure treatment integrity, they are in a better position to make final decisions regarding intervention implementation. Because the latter point is also a potential problem (Gutkin & Conoley, 1990), it is incumbent on consultants to work with consultees to ensure that these decisions are made in an informed and carefully thought-out manner. Consultants also have primary (but not sole) responsibility for (a) ensuring that the atmosphere remains non-evaluative, (b) identifying and presenting interventions for possible implementation in many cases, and (c) developing the evaluation plan. Within the cooperative partnership, then, possibilities are increased so that more creative solutions to problems will emerge, consultee ownership and commitment to carrying out interventions will be enhanced, and consultee self-efficacy will be improved.

Finally, key to understanding the cooperative partnership is to avoid catching the "egalitarian virus" (Barone, 1995). In explaining his failure to challenge a teacher's claim that "peanut butter cures attention-deficit hyperactivity disorder" (p. 35), school psychologist Stephen Barone proposed that a disease he termed the "egalitarian virus" paralyzes otherwise competent professionals, causing them to wither in the face of strong—but not necessarily informed—opinions. According to Barone, unrealistic ideas regarding the display of expertise permeate public education today; these include the beliefs that the specialized expertise of each staff member is directly interchangeable with that of any other, and that any person's opinion should be afforded *equal* rather than *due* consideration. The implication for consultants who engage in cooperative partnerships is to act as content experts when necessary and to not downplay their specialized knowledge but, at the same time, to attempt to understand and appreciate the unique strengths and weaknesses consultees bring to consultation.

RECIPROCAL INTERACTIONS

The principles regarding the reciprocal nature of consultative interactions are derived from Bandura's (1977) social learning theory and philosophy of reciprocal determinism. Indeed, these two paradigms serve as an overarching "meta-theory" underlying consultation practice (Zins, 1988). Unidirectional influence approaches usually have predominated the interactions between psychologists and those they seek to assist (Tyler, Pargament, & Gatz, 1983), but they do not adequately reflect the complexity of the consultation process. According to Bandura's model, consultants', consultees', and students' functioning result from the continuous and reciprocal interactions among behavioral, personal, and environmental factors. During the interpersonal exchanges that constitute consultation, participants draw from available power bases and exert influence on one another and their beliefs, attitudes, and behaviors can be altered as a result (Erchul & Raven, 1997; Reardon, 1991). The challenge for consultants is to maintain a cooperative partnership while at the same time exerting interpersonal influence, and only recently have some researchers agreed that the consultation relationship can be simultaneously collaborative and directive (Erchul, 1999; Gutkin, 1999a, b). Consultants accomplish this dual goal by establishing an atmosphere of mutual respect and trust, and by moving the process along through appropriate interviewing techniques. Consultees influence consultants primarily by specifying the assets and constraints of their role, the students, and the setting. Students likewise influence consultants and consultees as well as the entire system. "Therefore, understanding and changing the functioning of a consultee or client must focus on the interlocking relationship of these three [behavioral, personal, and environmental] factors, not on a single dimension" (Brown & Schulte, 1987, p. 283).

SYSTEMATIC PROBLEM-SOLVING PROCESS

Problem solving proceeds through an orderly, systematic sequence of steps, as discussed in detail later in the chapter (see Table 1), and the process is dynamic, evolving, flexible, and cyclical in nature (Kurpius & Lewis, 1988). The consultant guides the overall process, but the active, joint involvement of all participants is essential to maximize the potential that successful solutions will be developed and implemented. Moreover, formal, written documentation is kept regarding intervention development and outcomes in order to foster follow-up efforts and to increase accountability.

Table 1. Consultative problem-solving process

Establishment of cooperative partnership

- Promote understanding of each other's roles and responsibilities
- Avoid the egalitarian virus

Problem identification and analysis

- Define problem in behavioral terms and obtain agreement with consultee
- Collect baseline data regarding problem frequency, duration, and/or intensity and conduct task analysis as needed
- Identify antecedent determinants of the problem behavior
- Identify consequences that may maintain the behavior
- Assess other relevant environmental factors
- Identify all available resources

Intervention development and selection

- Brainstorm range of possible interventions
- Evaluate the positive and negative aspects of the interventions
- Select intervention(s) from the alternatives generated

Intervention implementation, evaluation, and follow-up

- Clarify implementation procedures and responsibilities
- Implement the chosen strategy
- Evaluate intended outcomes and any side effects
- Program generalization, plan maintenance, and develop appropriate fading procedures
- Recycle and follow-up as necessary

ECOBEHAVIORAL PERSPECTIVE

The behavioral paradigm has dominated the consultation field in recent years, but ecological/systems theories are now offered as a means of expanding traditional behavioral approaches (Gutkin, 1993). Both make important contributions to understanding the process.

Behavioral theory provides the experimental rigor and methodology necessary to concisely identify and measure problems, analyze forces influencing problem situations, and evaluate intervention outcomes. In addition, there is an extensive array of behavioral interventions with documented success available for implementation through the consultation process (Elliott & Busse, 1993).

Ecological and systems perspectives offer a useful framework for more broadly conceptualizing the setting or organizational context within which consultation occurs, and they expand the goals of traditional case-centered consultation. The connection between a problem and the system variables that may be contributing to it or preventing its resolution must be examined. This perspective widens the focus beyond the individual child to also include peers, family, teachers, classrooms, curricula, schools, community, other system levels, and so forth. Consequently, a wide array of factors that may be contributing to the problem is always considered in identifying problems and in developing interventions.

MEANS OF EMPOWERMENT

The empowerment philosophy in contemporary consultation "requires different assumptions and behaviors on the part of the consultant than does traditional case-centered problem solving" (Witt & Martens, 1988, p. 213). This ideology recognizes more explicitly that consultees and consultee systems already possess or readily can develop most competencies necessary to deal with student- and system-related problems, given the right opportunities and knowledge of available resources (Rappoport, 1981). They have a basic level of competence, but not necessarily the technical knowledge or skills to solve a particular problem. Thus, consultees' failure to solve problems is often a reflection of the system's failure to create opportunities or to provide support for the consultee to exhibit these skills, rather than simply an indication of their lack of knowledge about how to deal with the problem. The implications for consultants are significant. Their role becomes one of helping consultees to clarify needs and locate resources, and of ensuring that opportunities are available to enable consultees to engage in self-sustaining behaviors to resolve problems. Cast in social power terms, consultants need to harness their own power to enable consultees to be more powerful and influential (Erchul & Martens, 1997).

ENHANCEMENT OF STUDENT WELL-BEING AND PERFORMANCE

Although consultation usually focuses on improving consultees' skills and performance or changing their behavior, the ultimate beneficiary is always intended to be the student. To arrive at this goal, however, it is often appropriate for the entire school district or some segment of it to be the initial target of change, as in an organization development program (e.g., Ikeda, Tilly, Stumme, Volmer, & Allison, 1996). At other times, the focus might be even broader and involve interagency collaborations (e.g., McMahon, Ward, Kline Pruett, Davidson, & Griffith, 2000).

OTHER CHARACTERISTICS IMPLICIT IN DEFINITION

The problems addressed are always *work- or care giving-related* rather than personally focused as in counseling. In addition, material discussed is considered *confidential* by consultants, consultees enter into consultation *voluntarily*, and the consultative relationship is *temporary*. Gutkin and Curtis (1999) have discussed these issues as well as other core characteristics of consultation in great detail.

Prerequisite Competencies and Assumptions of Consultation Practice

In addition to a general knowledge of psychological principles and techniques (e.g., human learning, ethics, social bases of behavior, systems theory, research methodologies) and a familiarity with the educational system (e.g., teaching strategies, school operation and organization), there are other prerequisite competencies to effective consultation practice.

PREREQUISITE COMPETENCIES

A *sense of self-awareness* with respect to feelings, beliefs, thoughts, impact on others, and a personal clarity regarding one's values and theoretical bases is helpful to consultants (O'Neill & Trickett, 1982). Because a large aspect of the consultation process involves interpersonal interaction and influence, consultants must be aware of their own interpersonal styles, biases, and values, and of how these can affect their own perceptions of problems, as well as influence consultees and the problem-solving process.

Similarly, *good interpersonal and communication skills* are critical because consultation relies heavily on the interpersonal influence process to accomplish its goals. Consultants need, for instance, to be active listeners and to utilize effective questioning techniques to extract necessary information from consultees and to develop clear conceptualizations of problems. Further, the establishment of warm, caring, and understanding relationships is as important in consultation as it is in counseling.

Knowledge of intervention technology, both individual-focused and organizationally focused, likewise is an essential competency, but one that has been largely neglected in the consultation literature (Heron & Harris, 2001, is a notable exception). Gutkin (1981) found that more than two-thirds of the reasons consultees sought assistance were related to their lack of knowledge and skill in resolving problems, although an empowerment framework for categorizing these reasons was not employed in this study. The implication is that process skills are important but not sufficient for resolving most issues in consultation. Problem-solving and applied behavior analysis skills are also critical. Further, the goal of consultation is to promote application of effective interventions by consultees, which suggests that consultants must be knowledgeable about empirically validated techniques (e.g., Kratochwill & Stoiber, 2000; Stoiber & Kratochwill, 2000; Task Force on Promotion and Dissemination of Psychological Procedures, 1995). Unless consultants are successful in this endeavor, schools will be less likely to use this technology to benefit students, no matter how potentially effective it is (Wolfe, 1978).

An *understanding and knowledge of schools as organizations and of organizational functioning* is necessary for an ecological, systems perspective. Too often, school psychology training and daily practice tend to focus on the assessment and remediation of individual student-related problems, and consequently do not attend to more global and macro-level variables that exert significant influence. Thus, "consultants need an understanding of the workplace [school] not only as a technological system but also as a complex social organization" (Gallessich, 1982, p. 5). School norms, values, philosophy, and organizational climate can greatly facilitate or impede the consultative process.

An *awareness and sensitivity to cultural, racial, ethnic, socioeconomic, and gender issues* are important social dynamics in the consultation process. These various sociocultural factors, although not often discussed within the context of consultation, can exert considerable influence on the communication process, development of trust, reciprocal and mutual understanding, and overall relationship development (Ramirez, Lepage, Kratochwill, & Duffy, 1998). In addition, they have been found to affect help-seeking patterns and utilization of services, attitudes toward self-disclosure, duration of treatment, and outcome of treatment (Gibbs, 1985; Lorion, 1978). Further, these issues can affect the power-authority dimension of consultation, especially when one participant is a member of a minority and the other of a majority group. Finally, these same dimensions can influence the expectations of consultants and consultees, and thus the types of interventions that are developed.

ASSUMPTIONS

In addition to the above competencies, several assumptions underlie consultation. First is a belief that most parents, teachers, and other school personnel usually *want to be involved in the problem-solving process*. We recognize that there is a subset of people who (a) wish to be told what to do rather than jointly develop interventions; (b) do not want to deal personally with the presenting problem for some reason, but rather desire and expect someone else to do it (e.g., want a child placed in a special program); (c) fail or refuse to recognize the existence of a problem situation and thus do not seek consultative assistance; (d) do not have the skills or interests necessary to implement various interventions; or (e) face organizational restraints that prohibit or minimize their participation in the process. In addition to these groups, there are potential consultees who expect the consultant to "tell them what to do" based on their experiences with helping professionals, when in fact they actually would like to be involved in the problem-solving process (Zins & Curtis, 1981). This group can best be dealt with through an educative process about consultation.

A second assumption is that *prevention and early intervention are advantageous* for most children. There is a growing, convincing body of literature that supports this assumption (e.g., Minke & Bear, 2000), although there remains a clear need for additional research regarding the preventive aspects of consultation. Third, as noted earlier, *a vast intervention technology exists* that can be applied to address the problems experienced by children and schools. The challenge is how to apply it within the constraints of the school setting.

Finally, all school psychological services to children and schools are *best provided through a consultative framework*. That is, virtually all requests for assistance in dealing with a problem should begin with consultation. Thus, services such as psychoeducational assessment and counseling are viewed as components of problem clarification or as interventions developed through consultation to solve the problem.

BEST PRACTICES

Consultative Problem-Solving Process

Problem solving is the essence of consultation. It includes a number of steps from relationship development to initial designation of the problem; development and implementation of an intervention plan; evaluation of goal attainment and plan effectiveness; and concludes with planning for generalization, maintenance, and follow-up (Bergan & Kratochwill, 1990). As described in the following pages, it is necessary to engage in multiple levels of problem analysis and intervention development during this process. Because consultation is an indirect service, it requires that changes be brought about on more than just the individual student level. Child-related difficulties often result, at least in part, from ineffective instructional or classroom management strategies or from other external to-the-child causes. Consequently, it is essential to remain aware of the link between changes in the environment or in consultees' behavior, and changes in the target student(s) (Hawryluk & Smallwood, 1986). Furthermore, although consultative interventions may involve multiple consultants and consultees and can occur at several organizational levels, the primary focus of our discussion is on individual students, consultants, and consultees rather than on broader levels of change.

An ecological/systems perspective provides participants with a framework for developing a broad conceptualization of problems and for examining the wide range of factors that could be contributing to a problem situation. As stated above, problem analysis includes a thorough assessment of consultee variables as well as other factors affecting student behavior. For example, inaccurate perceptions or expectations of a child's behavior by the consultee may contribute to a problem. Research in the area of attributions has found that teachers generally perceive problems to be caused by factors internal to the child or because of home variables (Medway, 1979). Although child or home issues may be part of the problem, they should not automatically be considered the only cause. Student-related problems usually result from complex and reciprocal interactions among the child's behavior and the environmental and/or instructional conditions that regularly exist in a particular classroom, school, and community. Therefore, as participants in the consultation process define and analyze problems, information should be gathered not only about the child and the immediate contingencies affecting his or her behavior, but also about the ecology of the classroom, school, and community, or the home environment itself. Obtaining a broader perspective of the problem and reconceptualizing important variables as within teachers' or parents' power to change, will have impact on their causal attributions and expectations for problem resolution, as well as on the range of intervention strategies considered.

ESTABLISHING A COOPERATIVE PARTNERSHIP

The overall consultation process begins with establishment of a cooperative partnership (Table 1). Relationship building is a critical element of the process, beginning with the consultant's initial entry into the school and continuing throughout the proceedings. When consultants and consultees meet for the first time, each participant attempts to become better acquainted with the other, they strive to create an atmosphere of mutual respect and trust, and together they develop a "working contract"; that is, a basic understanding of what will occur during consultation. The contract minimally specifies the roles and responsibilities of each party, expected activities, and anticipated timeline for the consultation.

Two points in the process require clarification. First, although the steps in problem solving are presented sequentially, they usually overlap and thus may not occur in this exact order. Also, because of space limitations, examples in this section primarily refer to one-to-one consultation occurring between a school psychologist and a teacher, but clearly are applicable to a wide range of situations (e.g., group and organizational consultation, family-school partnerships, system change efforts).

CLARIFYING THE PROBLEM

The second step is to define the presenting problem(s) in clear, concise, complete, and measurable terms. Because there is a level of interdependence that exists between the problem definition and the potential interventions (Gutkin & Curtis, 1999), the following objectives need to be considered during this phase. First, consultants should help consultees describe concerns, goals, and expectations in a behaviorally specific manner to the extent possible. Consultees often do not have clear conceptualizations of problems when they request assistance, and they consequently present information in vague, global terms. Through skillful questioning, paraphrasing, and summarizing, an array of variables associated with the problem can be brought to their attention and then defined in measurable terms (see guidelines in Table 2). The collection of baseline data is an essential component of this step. Often, it is expedient to divide a complex problem into its component parts, thereby helping to ensure that neither participant is overwhelmed, and that both can work toward a useful problem analysis.

Often more than one problem may be designated, in which case they must be prioritized according to the perceived level of concern. With respect to an individual student, target behaviors can be ranked based on: (a) behaviors considered to be physically dangerous to self or others, (b) positive low frequency behaviors in need of strengthening, (c) behaviors that can be naturally reinforced in the environment, (d) behaviors viewed as essential for development, and (e) behaviors that maximize functioning in a variety of settings. Further, all target behaviors selected should be consistent with developmental norms (see Kratochwill, 1985, for an excellent summary of issues in target selection).

Target behaviors must be defined in concise measurable terms. Consultants and consultees should agree about the definition, and it should be worded in such a way that both parties (and others) can reliably record its occurrence. For instance, if lack of motivation is identified as a problem, it could be operationally defined in terms of "number of spelling assignments completed on time each day in school, and percent of correct responses." This definition is specific, easily measurable, and understandable to all.

Although target behaviors are often some aspect of the child's behavior or performance, this does not imply that the child should be the only focus of the intervention. Consultees' perceptions, instructional variables, or aspects of the classroom or school ecology are often what is changed. For example, use of teacher praise and feedback, or opportunities for students to respond in the classroom may be altered. However, the effects of these changes ultimately are still measured in terms of student outcomes.

Questions may be raised during the problem identification (i.e., initial) interview that need to be answered by additional methods of assessment. Direct classroom observations, functional assessment, utilization of curriculum-based probes, analysis of student permanent products, or assessment of organizational communication, structure, or climate are among the procedures that may be considered to help answer these questions (Zins, Curtis, Graden, & Ponti, 1988).

PROBLEM ANALYSIS

Once the target behaviors are identified, a comprehensive functional assessment of the interaction that exists between the child's behavior and the environment is conducted (e.g., Witt, Daly, & Noell, 2000). The baseline data and results of the assessment procedures are key components of this step because they provide a first-hand look at the complex interactions that occur between students, consultees, and their daily environments. Temporal and situational antecedents that appear to contribute to the problematic behavior should be identified. In addition, situations during which the behavior of concern does not occur can be noted, and consequences operating to maintain the behavior can be recorded. When identifying consequences, consultants should obtain information on (a) whether appropriate positive reinforcement is given, (b) forms of inappropriate reinforcement or attention gained by exhibiting the behavior, (c) the schedules of reinforcement in operation, and (d) reinforcement histories.

Table 2. Guidelines for behaviorally oriented problem identification interview

1. Definition of the problem

- Specify vague general statements regarding the consultee's concerns. ("You say that Rob is aggressive toward other children. Can you give me some specific examples of his aggressive behavior?")
- Develop an operational definition of the problem. Define the problem in measurable terms. Make it specific enough that others will be able to recognize it when they see it.
- Collect information about the frequency and duration of the problem. ("How many times per day does Mary shout out in class? How long does each episode of behavior last and for what length of time has the problem been occurring?"). Baseline data should be collected.
- Assess intensity or severity of behavior. ("Describe what types of things Brian does when he throws a temper tantrum.")
- If more than one problem is presented, then prioritize and select one target behavior on which to work initially.

2. Identify antecedent determinants of the problem behavior

- Identify temporal and situational antecedents. ("Are there times of the day when the behavior occurs most frequently? In which settings does the behavior occur?")
- Identify the behavior of others that may trigger or maintain the problem behavior. ("It seems that whenever you are paying attention to other children John's disruptive behavior intensifies.")
- Identify and analyze conditions that alleviate the problem. ("Does Sue seem to work better when you have structured her independent seatwork time through the use of goal setting and a timer?")

3. Identify consequences that may maintain the behavior

- Explore positive consequences that currently are provided or could be instituted to improve behavior or performance. ("What do you do when Joe completes all of his homework?" "What things does Cindy really like to do?")
- Explore forms of inappropriate reinforcement or attention occurring.

4. Assess other relevant environmental variables

- Identify significant others in the child's environment and assess their attitudes, attributions, and expectations regarding the problem and the child in general.
- Assess the discrepancy between the child's behavior and expected behavior. ("Howard is out of his seat on an average of 15 times per half-hour period. How many times would it be acceptable for him to be out of his seat within this time period within your classroom?")
- Assess instructional variables and classroom or home routines.

5. Identify all available resources

- Identify the strengths of the child. ("What types of things does Lisa do well?" "In what subject areas is William succeeding?")
- Identify materials and human resources available for intervention (e.g., peer tutors, parent volunteers, special instructional materials).

Note. Adapted from Peterson (1968).

Relevant environmental and instructional variables that operate regularly within a child's classroom or the larger organizational context must also be identified and analyzed. For instance, a consultant could determine whether the teacher had developed a set of rules to establish consequences for particular behaviors, how consistently the rules are enforced, amount of reinforcement available to the child from sources other than the teacher, peer reactions to the target behavior, opportunities the student is given to respond (both oral and written), method and delay in providing instructional and behavioral feedback, and appropriateness of curriculum (Witt & Martens, 1988). For academic problems, a task analysis of student skills in a particular subject may be necessary through methods such as Curriculum-Based Assessment/Measurement, examination of permanent products, and think-aloud techniques. Teacher and/or parent perceptions and expectations also should be explored to help them understand the array of factors that could be influencing the child's behavior or performance. As a result, they may be more open to making needed changes in behavior management or in instructional strategies. Finally, other variables such as peer interactions, school policies, and community norms should be examined.

Instructional practices of teachers and daily classroom, school, and home routines also need to be clarified to obtain a broad ecological perspective. Many problems that appear to be individually based on closer examination may require systems-level intervention. Traditionally, however, not much attention has been given to the environments of children and the adults who function in the children's environments. Nevertheless, it is the adults, not the child, who primarily control the environment in which the child lives (Saxe, Cross, & Silverman, 1988). In addition, teachers may require help in operationalizing what is acceptable behavior or performance in the classroom so that reasonable goals for the child can be developed.

Finally, all resources that potentially could be utilized in the development and implementation of interventions must be identified. These include student strengths, aspects of the system that are helping the child be successful in other situations, and material and human resources (teacher, time, parents, peer and volunteer tutors, community support systems) available for intervention.

BRAINSTORMING AND EXPLORING INTERVENTION OPTIONS

Once the problem is clearly defined and analyzed, the organizational level of intervention must be determined. For example, a program could be developed for an individual student, or the focus could be on helping a teacher change instructional practices or behavior management strategies for an entire class. Likewise, to address the problem, the district's reading curriculum might be altered, its policy on possession of weapons could be modified, or community norms regarding teenage alcohol use targeted. When participants agree regarding the level of intervention, they then generate as many treatment options as possible. The cardinal rule of this phase is to avoid evaluating ideas until the brainstorming process is completed. There often is more than one way to resolve a problem, and by generating a number of possible solutions, the probability is maximized of identifying an intervention that is both effective and acceptable to the consultee.

Interventions usually consist of some form of environmental manipulation because (a) there is substantial research specifying what types of environments lead to effective teaching, parenting, and behavioral change; (b) all consultees routinely manipulate meaningful school and home environmental variables; and (c) most consultees do not have the skills to engage in non-environmental manipulations such as counseling. Examples of variables that can be considered for manipulation include reinforcement and punishment contingencies, curriculum content, instructional techniques, teacher behavior, peer and sibling behavior, physical arrangement of the home and classroom, and the school administration (Gutkin & Curtis, 1999).

SELECTING AN INTERVENTION

After a number of intervention ideas have been generated, each should be evaluated to determine potential benefits and risks, unintended side effects, and feasibility of implementation. There generally are no "packaged" solutions to problems. Because a taxonomy of interventions related to a corresponding taxonomy of diagnoses does not exist (Gutkin & Curtis, 1999), treatments selected during consultation are simply high probability hypotheses. After a careful analysis of the problem is conducted, hypotheses are formulated regarding what is eliciting and maintaining the behavior or situation, and intervention strategies are developed from this information. Although consultants guide the interpersonal interactions, oversee the problem-solving process, and maintain primary responsibility for providing adequate information about the various intervention procedures identified, all participants contribute to the process and the ultimate selection of strategies rests with consultees. The following guidelines are useful in generating and selecting interventions.

1. Implement positive intervention approaches before resorting to behavior suppression or reduction techniques in all but extreme cases.

2. Choose the least complex and intrusive intervention possible. To the extent possible and appropriate, the focus should be on helping consultees modify instructional variables or general behavior

management strategies. Alterations in existing techniques usually are less intrusive or aversive to teachers and parents than is learning a new procedure.

3. When a new skill must be developed by consultees, design it to fit into present structures and routines as much as possible.

4. Develop a pool of resources such as peer and volunteer tutors or community resources that can be utilized when changes in the classroom are not possible or not sufficient to resolve presenting problems.

5. Provide support and reinforcement to consultees for implementing the intervention. Because a behavior change on consultees' part often is required, consultant support will encourage their continued enthusiasm and adherence in treatment implementation.

6. Promote interventions that require less time, are not ecologically intrusive, and are perceived by consultees to be effective. These types of interventions tend to be more acceptable to consultees (Elliott, 1988).

7. Finally, focus intervention efforts on promoting change at the highest organizational level possible.

CLARIFYING IMPLEMENTATION PROCEDURES AND RESPONSIBILITIES

Just as the nature of consultation was clarified initially, the pragmatic aspects of implementation should be clarified once the intervention(s) is selected. First, the roles and responsibilities of all participants in delivering the intervention must be delineated and agreed upon. The specific techniques should be outlined in a step-by-step fashion and potential reinforcers identified (often through a formal reinforcer assessment). The time(s) of the day and the settings or subject areas in which the intervention will be implemented must be decided. At this time, consideration should be given to programming for generalization. Specific suggestions for maximizing the probability that behavior change will generalize across time, persons, and settings are provided later in the chapter. All aspects of the plan should be put in writing in at least outline form (some consultants use a written protocol format) so each person involved has a clear idea of his or her responsibilities. This written plan also serves as a record for accountability purposes.

IMPLEMENTING THE STRATEGY

Once the intervention plan is developed, consultants should keep in contact with consultees to aid in implementation, provide technical assistance, and reinforce consultees' efforts. Consultees often have questions about the details of the plan, unanticipated behaviors may arise, there may be unintended reactions from other children, or there may be changes in the school environment. As a result, even the best-laid plans may need to be altered. Further, consultants can enhance consultees' motivation by involving the consultees in goal setting, establishing a trusting and warm relationship, and demonstrating personal competence (Brown & Schulte, 1987). In addition, if the intervention requires consultees to learn a new skill or to make substantial changes in current practices, it often is helpful for consultants to model the procedure, observe consultees implementing it, and provide constructive, supportive feedback (e.g., Noell, Witt, Gilbertson, Ranier, & Freeland, 1997). All of these elements—ongoing contact, adequate training, and support—are crucial for increasing and ensuring treatment integrity and success.

Consultee resistance to the planned intervention still may occur, although it can be minimized through establishment of a cooperative, supportive partnership. However, consultants must remember that the consultation process may (a) require considerable consultee effort and time, (b) focus on consultee failure, (c) involve differing perspectives of desirable outcomes, and (d) not result in immediate problem resolution (Piersel & Gutkin, 1983). Because each of these possibilities is non-reinforcing for consultees at least on a short-term basis, it is understandable that resistance is often encountered. By being aware of the potentially negative aspects of consultation, consultants may be better prepared to deal with any resistance. Further, there are many legitimate issues that consultees face that may prevent them from being able to carry out interventions as planned, and it is incumbent upon consultants to become aware of those issues to the extent possible.

EVALUATING INTERVENTION EFFECTIVENESS AND FOLLOW-UP

There are several interrelated aspects in this stage of the problem-solving process, including determination of intervention effectiveness, generalization, fading, and follow-up.

Evaluation of Intervention Effectiveness. Once the intervention plan is implemented, it should be systematically and regularly monitored to ensure treatment integrity and to identify any unintended side effects. Of course, the evaluation plan should be agreed upon before intervention implementation begins. Generally, the same data collection procedures used to obtain baseline information can be applied again as a means of evaluation. These methods should be as simple and time efficient as possible so that a teacher, student, parent, or peer can easily use the system. Single-subject methodologies such as single phase, reversal, or multiple baseline designs are often used to evaluate intervention effectiveness. These evaluation procedures may suggest that (a) the intervention resulted in attainment of desired goals, thereby indicating that follow-up monitoring and/or generalization and fading procedures are needed, or (b) the intended outcomes were not reached entirely, suggesting the need to recycle through earlier problem-solving steps.

Generalization, Fading, And Follow-Up. Evaluation data will indicate the degree to which the intervention is producing the desired outcome. Once an effective and reliable procedure has been identified, the intervention can be extended to other settings or systematically faded.

Although there are many well-developed, validated techniques for bringing about behavior change, we know substantially less about how to maintain these gains. A number of suggestions, however, have been offered in the literature on how to program *generalization* as interventions are developed and as they proceed to be implemented (Meichenbaum & Turk, 1987). Selected reinforcers, for instance, should be naturally occurring events when possible, and techniques should be implemented in a manner that lends them to fading or to greater transfer of control to the student (i.e., self-management approaches). Students and parents should take an active role in intervention development when possible and appropriate, and efforts should be made to help them understand the usefulness and relevance of the intervention to their lives. Training should take place in a number of settings using multiple tasks and trainers. Finally, opportunities to confront and deal positively with failure or mistakes also should be built into the intervention procedures.

Interventions that include specific prompts or reinforcement contingencies need to be *faded* systematically once the child is performing at desired levels. It is important to withdraw prompts or reinforcement in small steps rather than all at once to ensure maintenance of treatment gains. Fading can consist of increasing the amount of time before a child can earn a reinforcer, increasing task demands to earn a reinforcer, or decreasing the number of prompts given to children to elicit performance. If at any step in the fading process the student's behavior begins to deteriorate, reinforcement or prompting should revert to the previous level. Once the child's behavior stabilizes again for a reasonable period of time, fading can be continued.

The importance of *follow-up* by consultants during this stage is critical, although often neglected. Follow-up helps ensure that intervention procedures are being implemented correctly, and it can address the issue of unintended outcomes. When interventions provide ineffective or unreliable outcomes, consultants should observe the intervention in operation and conduct a functional assessment of the current situation to determine what conditions might be contributing to the non-attainment of the desired goals. Oftentimes, modifications in the existing plan suggested through corrective feedback are all that are necessary to increase ease of implementation, improve intervention effectiveness, or counteract unanticipated student responses. If the alterations do not result in better outcomes, then a new strategy should be sought, once again through the problem-solving process.

INFLUENCES ON THE CONSULTATION PROCESS

Central to the success of the consultation process are the issues of treatment acceptability, adherence, and integrity. Consideration of these issues, along with establishment of a cooperative partnership, can be major factors in intervention success, as well as in decreasing or avoiding resistance. *Acceptability* refers to judgments or beliefs of consultees and students about whether a treatment is "appropriate, fair, and reasonable for the problem or client" (Kazdin, 1981, p. 493). If participants like the intervention (i.e., find it acceptable), then they may be more likely to use it or to carry it out correctly (Wolfe, 1978), although it has been shown recently that pretreatment ratings of acceptability correlate only .30 with actual plan implementation (Martens, Kelly, & Diskin, 1996). *Adherence* involves the willingness of (a) consultees to carry out interventions to their completion and (b) students to engage in certain behavior changes indicated in the intervention plan (Meichenbaum & Turk, 1987). *Treatment integrity*, as mentioned earlier, refers to the extent to which consultees implement the intervention plan as intended (Gresham, 1989). Elliott (1988) proposed that the elements of acceptability, adherence, and integrity are reciprocally dependent; that is, they influence and are influenced by one another. Adherence and integrity are the two elements that link intervention use with effectiveness.

Not only is it important for interventions to be carried out, but the quality of the process by which they are delivered is also of concern. Thus, in addition to treatment integrity, implementation quality includes several additional key elements: (a) the treatment dosage or the frequency and duration of the intervention received by the target, (b) qualitative aspect of how the intervention was delivered (e.g., affective conditions under which the intervention was provided), and (c) participant (e.g., child) responsiveness to the intervention (Durlak, 1998). There may be significant differences between how the treatment was planned and how it actually was implemented, and these discrepancies must be monitored to increase effectiveness.

Because consultation is an indirect service and consultees almost always implement interventions, there are two levels of acceptability and adherence related to the process. The first involves the extent to which the consultees are actively involved in carrying out a mutually acceptable course of action to produce a desired behavior change in children. The second level involves the extent to which children are involved in the process and cooperate with the treatment plan implemented by the consultee (Meichenbaum & Turk, 1987). Further, there are certain factors related to treatment integrity, including the complexity of the intervention, time required to implement the plan, materials or resources needed, number of treatment agents involved, perceived and actual effectiveness of the intervention, and consultees' motivation, that affect implementation (Gresham, 1989).

When interventions are not followed or result in failure, consultants most often cite consultee variables such as motivation or skill as the cause (Martin & Curtis, 1981). Although consultee motivation may play a role in the success or failure of consultation outcome in some cases, it is not the predominant variable nor is it generally within the consultant's sphere of control. As indicated in Table 3, there are numerous factors that influence both adherence and treatment integrity. Although correlational in nature, these factors can provide useful guidelines for consultants interested in enhancing both adherence and treatment integrity on both consultee and student levels. It is evident from the literature, for instance, that relationship variables are of crucial importance. Adherence can be improved and resistance decreased through establishment of a supportive, cooperative partnership characterized by open communication. As mentioned previously, efforts should be made early in the process to clarify consultee beliefs and expectations about the consultation process and about intervention options and outcomes. In addition, discrepancies between consultants' and consultees' causal attributions for problems need to be resolved as they clarify the problem (Zins, 1985). And, systems-oriented consultants must also examine how their interactions, skills, attitudes, and beliefs may have contributed to the lack of success.

Other factors that affect treatment adherence include characteristics of the intervention procedures chosen and the extent to which clients (children) are involved in the process. A related issue is that of consultants' adherence (Meichenbaum & Turk, 1987). Consultants need to be aware of their own beliefs regarding their ability to help improve consultees' and clients' adherence, make efforts to monitor their own interactions with consultees, and develop the type of consultative relationship that maximizes the probability of adherence. Finally, because consultation sometimes results in short-term negative outcomes for consultees as noted earlier, the importance of providing support and encouragement is underscored.

ORGANIZATIONAL AND SYSTEM-WIDE CONSULTATION

School consultation is not limited to one-to-one interactions between a consultant and a consultee, or to

Table 3. Examples of factors affecting treatment adherence and integrity

Client (student) variables

- Belief that a problem exists
- Belief that the problem could have a negative impact on the student
- Belief that participating in the intervention will help the student
- Perceptions regarding not having a choice about being treated

Consultee variables

- Beliefs about potential efficacy of the intervention
- Understanding of the consultative process
- Satisfaction with the relationship with the consultant
- Misconceptions held
- Cultural beliefs and values
- Opportunities available to exhibit skills
- Beliefs about ability to carry out the intervention
- Personal motivation to resolve the problem
- Skills in describing problem situations and carrying out interventions
- Perceptions of consultant's expertise and competence

Consultant variables

- Theoretical orientation and values
- Skills in problem solving
- Technical competence in intervention development and evaluation
- Understanding of organizational functioning and change
- Motivation and enthusiasm
- Self-awareness and understanding

Relationship variables

- Interpersonal and communication factors
- Discrepancies between consultant and consultee attributions
- Participant sensitivity to cultural, racial, ethnic, and gender issues
- Extent of cooperation or mutual participation in process
- Continuity of involvement
- Extent of support and follow-up provided

Treatment variables

- Complexity of the intervention
- Time and resources required to carry out the interventions
- Intrusiveness of intervention relative to established regularities
- Duration of intervention
- Number of behavior changes that are made at once
- Number of treatment agents involved
- How soon behavior change is observed

Organizational variables

- Openness of social/organizational climate
- Opportunities and support provided for change
- Length of time until assistance is provided
- Perception of organizational support
- Time and resource availability
- Principal's leadership behavior

Note. Adapted from Gresham (1989), Gutkin (1986), Meichenbaum & Turk (1987).

behavioral change in individual students (although those are the foci of this chapter). Consultation may also involve simultaneous problem solving with parents and teachers, as in conjoint behavioral consultation (Sheridan, Kratochwill, & Bergan, 1996). At other times consultation is expanded to include groups of consultees, an entire school, or even a school district. Consultants increasingly are focusing on larger organizational issues to maximize and expand their influence, and to deal with problems that truly are systemic in origin. The same problem-solving procedures described earlier are followed in these instances, but, of course, there is a different focus, other types of interventions are developed, and there may be more people involved. However, behavior analytic and social learning procedures continue to be relevant. Examples of organizational consultation include involvement in the evaluation of a district-wide program for social and emotional learning, establishment of a smoking prevention program in a middle school, development of a program for senior high students to encourage car safety belt use and avoidance of alcohol, implementation of a tutoring program utilizing the services of volunteer senior citizens, and initiation of a health promotion program for school employees.

Over the last decade increasing numbers of schools have implemented consultation on a system-wide basis through intervention assistance (sometimes called prereferral) programs (Zins et al., 1988). These programs are a means to provide assistance to students in mainstream settings before a referral is made for special education assessment. Unlike most forms of assistance in schools, these services are available to all students and do not require the assignment of potentially stigmatizing labels for service. As a result, more students can be served, services are provided on a timelier basis, communication among involved staff can be enhanced, and a wide variety of interventions can be developed (Zins et al., 1988).

There are many variations on how intervention assistance programs have been organized and delivered (see Zins, Heron, & Goddard, 1999). However, the more comprehensive programs generally feature a number of levels of problem-solving help: collegial support among teachers; consultation with specialists such as school psychologists, special educators, and/or speech and language therapists; and group consultation with intervention assistance teams composed of individuals such as a school psychologist, special educator, general educator, administrator, other special services personnel (e.g., nurse, counselor), and parents (and children). Although additional investigation of this process is needed, research to date suggests that these programs are "a promising method for delivering preventively-oriented school psychological and educational services" (Zins et al., 1999, p. 810).

SUMMARY

As consultation continues to become a major aspect of many school psychologists' jobs, it is critical for them to keep abreast of the latest theoretical and empirical knowledge of this emerging field. The knowledge base of effective consultative interactions, systems-level influences, and evaluation techniques is expanding quickly, and this chapter represents an integrative summary of many of the most important of these recent developments. Included was a review of the essential aspects of consultation practice, including its emphasis on a cooperative partnership, a preventive and empowering ideology, consideration of systems issues and of the reciprocal and interdependent nature of the interactions, implementation issues, and a review of the most important dimensions of the problem-solving process. Our intent was to succinctly review the essential information needed to effectively engage in consultation. Ultimately, it is hoped that improvements in consultation practice will result in school psychologists being identified with consultation-based services that focus on intervention design rather than with traditional IQ testing directed toward special education identification and placement, so that successful outcomes for children occur with increasing frequency.

ANNOTATED BIBLIOGRAPHY

Brown, D., Pryzwansky, W. B., & Schulte, A. C. (2001). *Psychological consultation: Introduction to theory and practice* (5th ed.). Boston: Allyn & Bacon.

A very useful source for those who seek to develop the essential knowledge and skills of consulting. This text examines various models of practice and presents in detail the stages and processes of consultation. The chapters concerned with consulting with teachers and parents seem especially germane to the practice of school psychology.

Caplan, G., & Caplan, R. B. (1999). *Mental health consultation and collaboration*. Prospect Heights, IL: Waveland Press. (Reprinted from Caplan, G., & Caplan, R. B. (1993). *Mental health consultation and collaboration*. San Francisco: Jossey-Bass.)

This book is a revision of Gerald Caplan's (1970) seminal work, *The Theory and Practice of Mental Health Consultation*, one of the most frequently cited books within school psychology. Besides updating the mental health consultation model, the Caplans describe mental health collaboration and argue that internal consultants such as school psychologists should use collaboration rather than consultation.

Erchul, W. P., & Martens, B. K. (1997). *School consultation: Conceptual and empirical bases of practice*. New York: Plenum.

The authors review and integrate the most conceptually useful and empirically supported principles from the consultation literature. They then propose that the effective practice of school consultation involves the accomplishment of three interrelated tasks: problem solving, social influence, and professional support and development.

Gutkin, T. B., & Curtis, M. J. (1999). School-based consultation theory and practice: The art and science of indirect service delivery. In C. R. Reynolds & T. B. Gutkin (Eds.), *The handbook of school psychology* (3rd ed., pp. 598–637). New York: John Wiley.

This well-referenced chapter provides a comprehensive overview of key issues associated with consultation within the field of school psychology. The authors' coverage of the rationale for consultation, major approaches to school consultation, and critical presentation of contemporary and future issues is particularly noteworthy.

Zins, J. E., Kratochwill, T. R., & Elliott, S. N. (Eds.). (1993). *Handbook of consultation services for children: Applications in educational and clinical settings*. San Francisco: Jossey-Bass.

Following the editors' overview of the history and current status of consultation, chapter authors review conceptual foundations, models, processes, evaluation considerations, practice issues, and training approaches pertaining to the field. The book is the most complete source of information for the school-based practitioner or researcher, and also contains extensive references that readers may consult for additional information.

42 Best Practices in Operating Pre-Referral Intervention Teams

Joseph F. Kovaleski
Cornwall-Lebanon (PA) School District

OVERVIEW

For over a quarter century, the role of the school psychologist as consultant to teachers and administrators has been emphasized as a professional practice (Ysseldyke, Reynolds, & Weinberg, 1985; Ysseldyke, Dawson, Lehr, Reschly, Reynolds, & Telzrow, 1997) and as a subject of research literature (Zins & Erchul, 1995). At this point, many school psychologists are actively involved in teacher consultation.

Originally practiced in a one-to-one (dyadic) arrangement, many school psychologists now find themselves performing school consultation in a team format. This trend began in the 1980s when consultation teams were proposed as a method to increase teacher effectiveness and provide support for students who displayed classroom difficulties (Graden, Casey, & Christenson, 1985). Fueled by an alarming increase in the numbers of students identified for special education, particularly in the learning disabilities category, the popularity of school-based teams increased as educators sought methods to curtail the perceived over-identification of students with disabilities. Many school systems began to develop consultation teams under such titles as intervention assistance teams and child study teams. By the late 1980s, many states required team consultation as a pre-condition for referral for a full and individual evaluation for eligibility for special education. Carter and Sugai (1989) reported in a national survey that 23 states required and 11 others recommended pre-referral interventions, which were most commonly provided in team formats. Simultaneously, a substantial literature developed regarding pre-referral interventions and teams in particular. (For comprehensive reviews, see Nelson, Smith, Taylor, Dodd, & Reavis, 1991; Ross, 1995; Safran & Safran, 1996; Schrag & Henderson, 1996; and Sindelar, Griffin, Smith, & Watanabe, 1992.)

Fuchs, Fuchs, and Bahr (1990) defined pre-referral intervention as the "... teacher's modification of instruction or classroom management to better accommodate a difficult-to-teach pupil without disabilities" (p. 128). Pre-referral teams typically consist of groups of teachers and/or specialists who gather to solve classroom problems for students who are identified by classroom teachers. Types of membership can be differentiated according to the extent to which the team consists of classroom teachers only, or is enhanced by information from specialists (e.g., school psychologists, special education teachers, guidance counselors). The teacher assistance team (TAT) model (Chalfant, Pysh, & Moultrie, 1979) featured teachers assisting other teachers in a team format, which allowed for the brainstorming of strategies calculated to address the problem. Other models utilized specialists who were specially trained or who had particular types of expertise as adjuncts to the team of teachers (Batsche & Knoff, 1995b; Fuchs et al. 1990; Graden et al., 1985). Rosenfield and Gravois (1996) included teachers and specialists in an instructional consultation team format that served as a vehicle for incorporating precisely designed instructional strategies into a teacher-consultation process. During the 1990s several states, including Iowa (Tilly, Clark, Atkinson, & Flugum, 1992), Pennsylvania (Kovaleski, Tucker, & Stevens, 1996), Kansas, Vermont, and Ohio, mandated pre-referral teams that featured specialists and teachers using a problem-solving process.

It is acknowledged that many argue that the team assistance process should be disconnected from special education. Using the term "pre-referral" is said to imply that these procedures serve only as perfunctory last steps prior to an inevitable referral for an evaluation for special education eligibility. It is further argued that the focus of these team-based activities should be on the improvement of general education. In spite of these legitimate conceptual concerns, the term, "pre-referral teams," will be used in this chapter for the following reasons. First, there is no consensus in the field as to what these teams should be called (e.g., intervention assistance teams, instructional support teams, child study teams). All of the extant terms have developed different connotations, and no one term leads directly to an understanding of what can be considered as best practice at this time.

A second reason to maintain a connection with special education is that a student's response to a team-supported intervention should be assessed prior to consideration for special education. Kovaleski and Prasse (1999) argued that the requirement of the Individuals with Disabilities Education Act (1998) regarding the determination as to whether a student's problems are due to a lack of instruction can be most effectively operationalized through an assessment of the student's response to intervention. Given the historic concern that norm-referenced tests alone can not reliably discriminate a disability from academic underachievement (Ysseldyke, Algozzine, Shinn, & McGue, 1982), it is important that the screening process include this assessment prior to referral for further evaluation. This assessment is most effectively conducted by a team of school personnel that includes the student's teacher.

In using the term pre-referral team it is not implied that schools should wait until students are on the cusp of a referral to special education to utilize a team-based, teacher support process. A major benefit of these teams has been their emphasis on early intervention. Hartman and Fay (1996) reported that 85% of students served by instructional support teams did not need further evaluation for special education. However, with proper documentation of results, the data collected during the intervention can later be used as part of a full and individual evaluation if necessary.

The purpose of this chapter is to articulate those best practices that have been identified to increase the effectiveness of pre-referral teams. These practices are based on three sources: (a) the conceptual literature on teacher consultation, (b) results of studies conducted on pre-referral team effectiveness, and (c) reports from states that have mandated pre-referral teams. After a description of the basic considerations that school psychologists and other specialists need to bring to the pre-referral team structure, the identified best practices will be divided into systemic factors and process factors. Systemic factors are not directly related to consultant functioning or skills, but are important from an organizational perspective for the process to be effective. Process factors are directly related to the functioning of school psychologists and other specialists who serve on pre-referral teams.

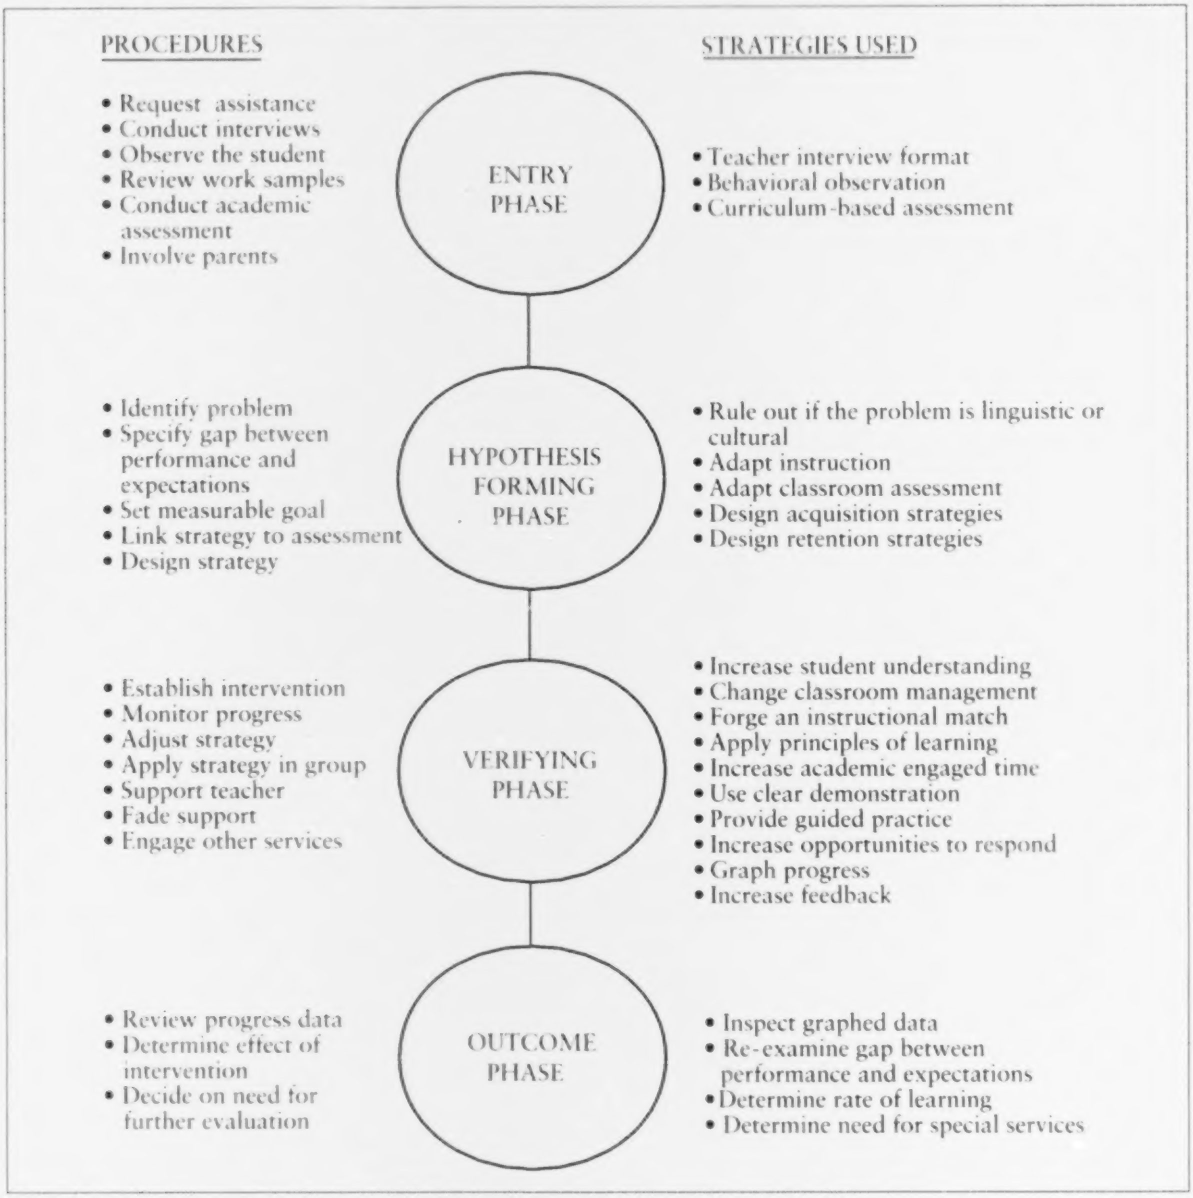
BASIC CONSIDERATIONS

In this chapter it will be assumed that school psychologists have training and experience in a number of professional skills that are critical to effective functioning in a pre-referral team format. While these skills will be summarized briefly in this section, the reader is referred to the indicated primary sources for detailed information.

The first set of competencies needed by school psychologists who participate on pre-referral teams are those of dyadic consultation, particularly the skills of behavioral consultation (Bergan & Kratochwill, 1990). These competencies include both verbal-interaction skills, such as assisting a teacher to give a more precise definition of the presenting problem, and the collaborative posture considered to be essential to the consultation process (Rosenfield, 1987; Zins & Erchul, 1995).

It is also assumed that school psychologists who participate in pre-referral teams have an understanding of the problem-solving model (Deno, 1995). Figure 1 illustrates a pre-referral team process that incorporates problem solving as its core process. Also essential are skills that are required for effective use of problem solving in a team format. These supporting competencies include curriculum-based

Figure 1. The pre-referral intervention team process



PROCEDURES
STRATEGIES USED
• Request assistance
• Conduct interviews
• Observe the student
• Review work samples
• Conduct academic assessment
• Involve parents
ENTRY PHASE
• Teacher interview format
• Behavioral observation
• Curriculum-based assessment
• Identify problem
• Specify gap between performance and expectations
• Set measurable goal
• Link strategy to assessment
• Design strategy
HYPOTHESIS FORMING PHASE
• Rule out if the problem is linguistic or cultural
• Adapt instruction
• Adapt classroom assessment
• Design acquisition strategies
• Design retention strategies
• Establish intervention
• Monitor progress
• Adjust strategy
• Apply strategy in group
• Support teacher
• Fade support
• Engage other services
VERIFYING PHASE
• Increase student understanding
• Change classroom management
• Forge an instructional match
• Apply principles of learning
• Increase academic engaged time
• Use clear demonstration
• Provide guided practice
• Increase opportunities to respond
• Graph progress
• Increase feedback
• Review progress data

assessment (Gickling & Rosenfield, 1995) and curriculum-based measurement (Shinn, 1995), systematic behavioral observation (Hintze & Shapiro, 1995), linking assessment to intervention (Batsche & Knoff, 1995a), designing high-quality interventions (Tilly & Flugum, 1995), and facilitating treatment integrity (Telzrow, 1995). A further consideration is that the consulting psychologist has an understanding of the literature on effective instruction and the ability to design practical and meaningful interventions based on the research (Lloyd, Forness, & Kavale, 1998).

The premise of this chapter is that all of these components are necessary, but not sufficient, to produce effective team functioning that brings about meaningful outcomes for students in the form of increased academic achievement and/or decreased behavioral difficulties. In the next sections, systemic and team-process features, which are critical to the realization of these outcomes, will be presented.

BEST PRACTICES

System Factors

Many school psychologists have experienced frustration in their attempts to provide consultative services in school systems not receptive to it, frequently being relegated to traditional testing activities. Regardless of the psychologist's individual skills in consultation, there are a number of system factors that are necessary for pre-referral teams to be accepted in schools and to function effectively.

TEAM FORMAT

The most obvious question regarding pre-referral teams is whether a team is actually needed to produce effective classroom interventions. When Chalfant et al. (1979) originally articulated the concept of a team format for school-based consultation, they argued that benefits would accrue as teachers experienced support from their colleagues. Since that time, most systemic pre-referral efforts have included teams, including instructional consultation teams (Rosenfield & Gravois, 1996), instructional support teams (Kovaleski et al., 1996), and various types of school-based intervention teams (Bahr, Whitten, Dieker, Kocarek, & Manson, 1999). In addition to the support function described by Chalfant et al. (1979), providing pre-referral interventions in a team format allows for the development of a sense of mission and team spirit. Facilitating change in general education classrooms can be daunting work, and the team structure allows for members to support each other in the face of unavoidable resistance to change. While teams need to guard against becoming elite groups isolated from the general staff, it appears that teams are preferable to conducting pre-referral consultation on an individual practitioner basis. In Pennsylvania, when instructional support teams were deregulated, 89% of school districts maintained their teams as the way to conduct required pre-referral activities (Bickel, Zigmond, McCall, & McNelis, 1999).

PRINCIPAL LEADERSHIP

The involvement of the school principal in pre-referral teams has been somewhat controversial. The early TAT model included only teachers and excluded the principal from team problem solving on the basis of concerns that principals might inhibit the process because of their responsibility for teacher evaluation. It was imagined that teachers might fear identifying students for assistance because their principal would construe the request as an indication of ineffective instruction or an inability to manage the classroom. In contrast, more recent models (e.g., instructional consultation teams, instruction support teams) have incorporated the principal as a required and vital member of the team. Kruger, Struzziero, Watts, and Vacca (1995) found that administrative support was a critical aspect in the acceptance of teacher assistance teams by teachers.

There are a number of substantive reasons for involving principals in pre-referral teams. Part of the paradigm shift implied in pre-referral intervention is a move away from the search for pathology, that is, the underlying premise of the refer-test-place process, toward a focus on the examination and manipulation of instructional variables. The principal needs to demonstrate tangible support for this shift by attending pre-referral team meetings, articulating an expectation of instructional improvement, and fostering a collaborative atmosphere among the teaching and professional staff. Circumventing the process by appealing to the principal for testing cannot be considered an option. A clear message must be sent that in-class interventions need to be thoroughly implemented before special education eligibility can be considered. Rather than perceiving a request for assistance as a sign of teacher failure, principals need to communicate that the use of the process is a highly professional action.

Another important rationale for the active involvement of the principal in the pre-referral process is the need to coordinate instructional and support services. An important function of pre-referral teams is the coordination of the work of available personnel and services. The principal's role is to assure that these services are deployed in a seamless fashion by helping to allocate needed resources and by assuring that there is curricular and instructional overlap among personnel and processes. The principal needs to model flexibility and creativity in using existing personnel, and work against the often erroneous notion that innovative instructional approaches and personnel arrangements are in violation of existing laws and standards (Prasse & Schrag, 1999). It is also important for the principal to be the lead person in articulating the pre-referral process to the entire school, and assuring that classroom teachers receive sufficient training to use the process effectively. Finally, the principal needs to make connections between pre-referral process and other aspects of instructional improvement in the school and the district. Pre-referral intervention should not be viewed by staff as a stand-alone entity. It needs to be connected conceptually and procedurally with other professional activities and school-based initiatives.

MANDATING PRE-REFERRAL INTERVENTION

On a system level, pre-referral teams are adopted most comprehensively and maintained when they are required. Pre-referral teams have been quickly established in states and local systems where there are legal requirements through state regulations (e.g., Pennsylvania), or as a result of court action (e.g., Chicago's *Corey H* settlement, 1998). The important aspect of a mandate is that it tends to energize the attention and support of central office administration at the local level. Resources are allocated and policies changed when there is an understanding that there will be negative consequences for noncompliance (Conway & Kovaleski, 1998).

Ideally, the establishment of state regulations or local policies coincides with a perceived need to solve a problem by local officials. For example, in Pennsylvania, instructional support teams were established in 500 school districts over a five-year period with comparatively little resistance because the mandate coincided with a statewide concern regarding increased special education costs due to over-identification (Conway & Kovaleski, 1998). Pre-referral teams are a type of school restructuring that requires intense effort over a short period to ensure institutionalization. Few school districts, especially large systems, are able to maintain focus on any initiative that progresses on an incremental, school-by-school basis. While a statewide mandate is not necessary, and is by no means sufficient, to assure that the process is operated with sufficient quality to be effective, it clearly facilitates the administrative commitment needed to produce system-wide change.

ASSIGNMENT OF STAFF

School staff, including consulting personnel such as school psychologists, needs time to serve on pre-referral teams. This function needs to be identified by both central administration and the school principal as equally critical to other activities such as conducting evaluations for special education. Many school districts have addressed this issue by dedicating individual personnel to the pre-referral role. In Pennsylvania, support teachers were assigned on a ratio of one to 500–750 students on a full-time basis to conduct pre-referral activities. If other personnel share the consultative role, then a full-time equivalent corresponding to this ratio is needed. For example, in a school of 600 students, if pre-referral activities are conducted by a school psychologist and two other specialists, each of these personnel needs to spend about one third of their time dedicated to these activities. Consequently, their workload in other areas needs to decrease by the same percentage. Imagining that pre-referral activities can be added to already heavy caseloads of busy practitioners dooms the process to failure.

ENSURING ACCOUNTABILITY

Because pre-referral teams are typically not mandated, it is important for school districts that initiate pre-referral teams to build in an evaluation of the program to determine its impact. Demonstrating that pre-referral teams are effective in meeting the needs they were intended to address is critical in maintaining long-term support for the process. Before implementation, school districts should put in place procedures to collect ongoing data that can be used for program evaluation. These data take three forms. First, data on improvements in academic variables for individual students undergoing the pre-referral process should be gathered. For example, Kovaleski, Gickling, Morrow, and Swank (1999) showed that students who were served by instructional support teams displayed increases in time on task, task completion, and task comprehension when the pre-referral process was implemented with a high degree of fidelity. A second level of analysis utilizes school-wide indicators, such as numbers of students served by the process, numbers of students referred for special education evaluations, and numbers of students retained in grade. Hartman and Fay (1996) thoroughly described these measures in their analysis of the impact of instructional support teams. A third type of evaluation that uses surveys of teachers and parents who have utilized the pre-referral process can be beneficial, but should be considered as the least rigorous and valid of the three types. Satisfaction with the process may not necessarily be related to outcomes for students.

TRAINING

The skills required to conduct effective pre-referral teams are complex and are often not included in typical teacher-preparation programs. Consequently, meaningful and sufficient training for members of the team as well as the entire school faculty is a critical aspect of implementing this process. All team members need to be trained in the fundamentals of collaboration, including communication skills, team building and maintenance, and an understanding of team roles and responsibilities. Individual members need training in curriculum-based assessment, behavioral assessment, and differentiated instructional strategies.

The format of the training program is also critical. Effective implementation is usually not realized if the training consists solely of didactic, group presentations. Rather, on-site consultation that features actual demonstrations of the skills and guided practice with practitioners is needed. For example, individual student assessment that leads directly to the development of ideas for instructional strategies can be modeled with students in an actual classroom situation. Similarly, a developing team can receive *in vivo* guidance from a consultant during a team meeting. Practicing school personnel, like all learners, learn best by doing, and by receiving specific feedback.

Process Factors

The aforementioned system factors are necessary to create an environment in which pre-referral teams can function. Once these supports are in place, there are a number of factors that need to be accomplished for pre-referral teams to realize meaningful outcomes. Some of these factors have been well established in the consultation and problem-solving literature. Others are proposed as a result of recent experiences with pre-referral teams.

CREATING A DATA-BASED PROCESS

The history of school-based pre-referral teams can be described as an increasing infusion of information into a collaborative team process for solving problems. Early work with TATs was characterized by teachers assisting teachers through problem clarification, goal setting, and brainstorming of strategies, without the systematic use of data obtained about the student or instructional environment. More recent models, including instructional consultation teams (Rosenfield & Gravois, 1996) and instructional support teams (Kovaleski et al., 1996), have incorporated the systematic collection of student and classroom data into all stages of the process. In a survey of the most critical factors of the instructional support team process, Bickel et al. (1999) found that assessment procedures such as curriculum-based assessment were critical to the following aspects of the process: using multidimensional assessment procedures to identify the student's instructional level and to forge a match with instructional materials, using obtained data to design individualized interventions, and using ongoing progress monitoring throughout the intervention to determine the success of the intervention. Each of these aspects of data collection is critical to effective pre-referral functioning.

Using curriculum-based assessment in the initial stages of the process helps to identify the problem with much more precision than an initial interview with the teacher. Many students referred for academic, or even behavioral difficulties, are found to be working at a frustrational level on the classroom tasks they are assigned. Gickling and Rosenfield (1995) defined this level as less than 93% known material during independent work and less than 70% known material during direct instruction. Finding that students are well below these levels during the initial assessment usually lead to a straightforward choice of the classroom strategy. Adapting the instruction so that the percentage of known material is increased creates an improved instructional match that usually results in rapid improvement (Kovaleski et al., 1999).

While using baseline data to inform strategy development increases the probability that a successful strategy will be implemented, pre-referral teams have

641

found that even data-based strategy selection does not guarantee success. Consequently, these teams have effectively used graphed data for instructional decision making. Curriculum-based measurement techniques (Marston & Tindal, 1995) are particularly valuable when used frequently (e.g., twice per week), so that strategies can be altered if sufficient improvement is not observed.

SELECTING RESEARCH-BASED STRATEGIES

In the early literature on collaboration (e.g., Chalfant et al., 1979), brainstorming was used as a method for generating a bank of strategies to address the presenting problem. Teams were encouraged to "free wheel" and come up with as many diverse strategies as possible. The teacher would then be offered a choice as to which strategy would be adopted in the classroom. The basis for this procedure was the notion that teachers were more likely to implement interventions they found acceptable. However, given the advent of the extensive use of assessment data to guide strategy development, these procedures now appear to be unnecessary, or even counterproductive. Brainstorming may result in the generation of numerous strategies that have little empirical support and, therefore, little probability of improving student performance. Rather, based on the assessed data, pre-referral teams should focus on research-based strategies that have a demonstrated potency, leading to quick and meaningful changes in student performance.

An effective procedure for selecting strategies is empiric assessment (Braden & Kratochwill, 1997). Colloquially, this tactic has been termed the "Maalox™ approach." The concept refers to a physician, who, when presented with a patient describing gastrointestinal distress, prescribes a regimen of Maalox™ prior to conducting expensive and time-consuming diagnostic testing. Physicians take this approach because in most cases, Maalox™ works, avoiding further interventions. Applying the Maalox™ approach to schools, pre-referral teams are encouraged to attempt high-probability strategies that have demonstrated research support and are likely to show quick and effective results before conducting lengthy evaluations that may not lead to beneficial interventions. Thus, one important function of pre-referral teams is to maintain focus on objective research literature in regard to various instructional strategies.

ESTABLISHING THE INTERVENTION

An aspect of effective pre-referral team functioning that has not received attention in the professional literature is the need for consulting personnel to assist with the initiation of interventions in the classroom after the strategy is selected. In this procedure, the team member works with the student in the classroom in an individual or group format to "systematically search for what works" (Kovaleski et al., 1996). By taking a hands-on approach, the consultant assures that treatment fidelity is accomplished and models the strategy for the classroom teacher in a peer-coaching format (Joyce & Showers, 1982). For example, if the initial assessment showed that the student could recognize few sight words, the school psychologist might use a "fold-in" strategy (Gickling & Havertape, 1981) with the student in the classroom. Working for approximately 15 minutes per day over the course of a week, the psychologist could introduce new words, practice newly learned words, and chart the students progress to determine if the strategy were working.

This practice is a departure from the "just-talk" approach typically described in the consultation literature. Teams that do not have one of its members establish the intervention in the classroom will likely find lower levels of treatment fidelity and higher levels of teacher resistance. Unless there is ongoing support with the intervention, teachers will likely be uncomfortable with the intervention even if they are involved in the initial selection process. In contrast, having team members work directly in the classroom, for at least part of the intervention, serves to increase teacher acceptance and facilitate eventual incorporation of the strategy into the classroom routine.

INCORPORATING THE INTERVENTION

Having a team member establish the intervention in the classroom leads directly to the next step of effective pre-referral team practice, assuring that the team finds a practical way to incorporate the strategy into the teacher's day-to-day instructional routine. This step involves the team's working with the classroom teacher to develop a specific plan as to how the strategy that has been found to be effective in the early stages of the intervention period can be adopted by the teacher without further on-going support. It is important at this stage of the process for team members to be knowledgeable about the practical aspects of classroom teaching and the teacher's individual preferences for classroom instruction. Unless the team can determine with the teacher a viable method for incorporating the strategy into the teacher's large or small group instruction, the intervention has little chance of being maintained for the student. Along with establishing the intervention, this step is a significant departure from the more typical procedure of pre-referral teams of recommending a strategy and checking back later.

INVOLVING PARENTS

Many pre-referral teams have excelled in intensively involving parents of the students identified in the team process. In these schools, parents have provided information as part of the initial assessment, given input on the selection of strategies, and have participated in final outcome decisions. Teams have designed strategies for parents to use at home as part of the overall intervention for their children, and some have provided special training for parents in the instructional techniques most frequently utilized in the team process. Communication throughout the process and active involvement in the resolution of the difficulty have helped schools maximize the important roles parents play when their child has a problem.

Pre-referral teams must use caution when working with parents to not abrogate their due-process rights under IDEA. Parents have the right to a full and individual evaluation if they suspect that their child may have a disability. Teams should respond accordingly if a formal request of this nature is made. However, in many cases, when working in an early intervention mode, parents ask generically for help rather than request an evaluation *per se*. A prudent course of action is to fully inform parents of the procedures and benefits of pre-referral intervention while apprising them of their rights to a comprehensive evaluation. Many parents are willing to support a period of pre-referral intervention, especially if there is sufficient accountability through the setting of measurable goals from the outset of the process. In addition, it is important for pre-referral interventions to be time-limited. Fifty school days from the initial expression of concern by a teacher or parent to the completion of the process (including assessment, intervention, and evaluation of progress) is generally enough time to assure that the intervention has had time to work while protecting the parents against an unnecessary delay in conducting an evaluation, if needed.

SCREENING FOR FURTHER EVALUATION

Because one rationale for existence of pre-referral teams is to decrease the number of students in special education, many states and local school districts have required pre-referral teams as a prerequisite for the evaluation of students suspected of having disabilities. As was indicated earlier, Kovaleski and Prasse (1999) have argued that using pre-referral intervention as a screening for special education is an effective way to check for a lack of instruction, a requirement of IDEA. The role of the pre-referral team is to determine whether students who make sufficient progress during the intervention period are, in fact, displaying a lack of effective instruction rather than evidence of a disability. This determination can be based on the success of the team in producing improved performance for the student by using methods that are feasible in a general education setting. If the student makes tangible progress as a result of pre-referral intervention, then it can be concluded that the student was reacting to a lack of instruction, and has little need for specially designed instruction. In contrast, if the student fails to improve in response to a well-designed pre-referral intervention, then a lack of instruction is unlikely. Rather, the student is displaying more needs than can be met through general education services only. In making this determination, the pre-referral team can determine whether discrepancies in performance are the result of a lack of instruction and can be corrected without special education, two salient requirements of IDEA.

SUMMARY

There is strong support for school psychologists working in pre-referral teams to assist schools in developing high quality interventions for students who display academic and behavioral difficulties. While individual consultation skills are a necessary prerequisite for this work, the team format itself appears to be an important vehicle for assisting individual students and facilitating systemic change. Working in a team format during a pre-referral process requires the school psychologist to have skills in both consultation and in the team process itself. School psychologists can help school systems create organizational change when they position themselves as part of the group that is invested in school restructuring. School psychologists need to work closely with principals to support their site-based leadership of the pre-referral team and with central office administration in the development of a rationale and plan for change. Because of their expertise in both assessment and research procedures, school psychologists can also assist in designing accountability measures to appraise the results of the work of pre-referral teams.

On a process level, a salient conclusion of this chapter is that school psychologists need to move beyond a "just-talk" role in consulting with pre-referral teams. An effective pre-referral process requires the extensive use of curriculum-based and behavioral assessment. In addition to this assessment function, school psychologists need to become active members in establishing interventions in classrooms and helping teachers incorporate strategies into day-to-day teaching practices. These activities may be the most foreign to those school psychologists who have considered consultation to be largely an indirect-service activity. However, it appears clear that actively engaging with students and teachers in the classroom is critical if interventions are to live beyond their initial development. The extent to which school psychologists are willing to adopt this hands-on approach may not only impact the effectiveness of pre-referral teams but may also determine whether school psychologists are invited to participate at all.

43 Best Practices in Problem-Solving Team Structure and Process

Annette M. Iverson
University of Northern Iowa

OVERVIEW

School-based, problem solving teams (PSTs) that focus on intervention design and implementation have been functioning since the late 1970s. New and improved variations of PSTs continue to be developed in order to address various obstacles to team effectiveness. One major obstacle is the lack of process skills needed to effectively problem solve for interventions in teams. Someone needs to take the leadership role in assisting teams to develop process skills. School psychologists are a logical choice for providing such leadership. This chapter describes practices that school psychologists can use to facilitate team problem-solving processes. Processes are limited to team structure (e.g., allotted time, roles of members, team membership) and use of communication process skills (e.g., listening, including, refocusing) that support systematic decision making. This chapter is not about the content of problem-solving questioning or interviewing, data gathering, and other aspects of systematic decision making for intervention planning. These competencies are critical to the success of problem solving for interventions, and readers are directed to additional chapters of the text for pertinent information.

Team problem solving in schools takes many forms. One historic form is multidisciplinary teams that focus on the tasks of diagnosis and special education placement. A more recent form of team problem solving focuses on intervention planning with the goal of maintaining all children in the general education curriculum to the greatest extent possible.

Simply knowing that teams engage in problem solving reveals very little about their processes (Barnett & Zucker, 1990). Team processes, as defined here, are group structure and communication dynamics that enhance, or detract from, intervention planning and implementation. When problem-solving content changes (e.g., from diagnosis and special education placement decisions to intervention planning and maintenance in regular classrooms), processes must change, also, or goals will not be attained. Process is helpful in all forms of team problem solving. It is especially critical to consider when teams are attempting to set aside prior problem-solving forms and learn new skills.

History

Multidisciplinary teams were mandated as the decision-making body for special education entitlement when P.L. 94-142 was signed in 1975. Reasons for the team approach were to limit the decision-making authority of any one professional, to make sure different perspectives from diverse group members were considered, and to involve parents in decision making about their children.

Many school psychologists were educated and continue to be educated to participate in multidisciplinary teams that process referral problems from either a diagnostic perspective (e.g., Does the child have a disability?) or an administrative perspective (e.g., Does the child qualify for special education?) (Macmann et al., 1996). This approach represents a decision frame that has come to be known as the "test and place" approach to problem solving. Historically, the development of solutions or interventions in the "test and place" approach was viewed as part of the multidisciplinary team problem-solving process. The process generally yielded one common solution (i.e., placement in a special education program).

After 1975, teams that focused on intervention design were mandated or recommended by most states (Carter & Sugai, 1989). Pre-referral teams, student assistance teams, building assistance teams, teacher assistance teams, and similar names have been used to designate problem-solving groups that have as their goal the design of interventions to help children be successful in the general education curriculum. For clarity in communication, PSTs will be used throughout this chapter to refer to all groups who engage in processes that result in interventions. PSTs are distinct from traditional multidisciplinary teams (MDTs) that focus on diagnosis and placement. Disability diagnosis is rarely a goal of PSTs, and the question of special education entitlement is considered only in the final phase of ongoing problem solving.

There were no federally mandated models for accomplishing the intent of the law. Two major models emerged: (a) teams with broad participation and problem-solving approaches that placed the initiative for action in the hands of general education teachers and (b) teams that emphasized consultative approaches in which a specialist was the key provider to the referring general education teacher (Telzrow, McNamara, & Hollinger, 2000).

Barriers for broad participation teams were identified by Anderlini (1983) and Pfeiffer (1980) as:

1. A lack of systematic decision-making processes
2. A lack of interdisciplinary collaboration and trust
3. A lack of family involvement
4. A lack of education and training in team processes

It is the final barrier, lack of training in team processes, that is described here with best practice suggestions. Empirical bases for selecting team structure also are presented to help school psychologists guide schools in selecting the best fit for their culture and legal requirements.

Major Issues

School psychologists typically have the process skills to participate in MTD meetings when the goal is diagnosis and special education placement. However, when the decision frame changes to a focus on intervention design, many school psychologists are not sure what group processes to implement. Principals, teachers, parents, educational consultants, and other team members also do not know what the process looks like or sounds like.

One difference is that the questions and tasks of the team completely change (e.g., How can the instructional environment change to match the learner's needs?) (Macmann et al., 1996). A second difference is that group process skills must be used by all but often are unknown to team members. Members resort to trial and error, often with disappointing and frustrating results. Effective processes can make the difference between team members leaving the problem-solving meeting with intervention plans or without plans and, consequently, feeling their time was wasted.

RESEARCH ON TEAMS

Little research has been conducted on processes affecting the success of PSTs in schools. Fuchs, Fuchs, Harris, and Roberts (1996) conducted a 4-year study of team problem solving. They determined that broad participation teams were ineffective in terms of student outcomes and teacher satisfaction and, subsequently, reduced team membership to a consultant and consultee. Fuchs and Fuchs (1996) noted that broad participation PSTs were not based on empirical evidence of student outcome efficacy.

Welch, Brownell, and Sheridan (1999) reviewed refereed journals from 1980 to 1997 and found 18 articles on school-based PSTs. Over half were categorized as technical guides or position papers. Only one-third were empirical studies, and PST outcomes tended to be based on members' self-reports of satisfaction rather than student benefits. In a more recent study, Telzrow, McNamara, and Hollinger (2000) examined MDT problem solving and the relationship to student outcomes in 227 schools. Although each school submitted its single best case of the year, results indicated that reliable implementation of problem solving was not achieved. Years of MDT participation in problem solving were unrelated to reliable implementation, and benefits to referred students could not be determined.

Despite empirical evidence to the contrary, and armed primarily with anecdotal evidence, many proclaim the superiority of groups over individuals. Team approaches are based largely on a number of assumptions about the benefits of group decision making. Research suggests, however, that interacting groups are not likely to exceed the performance of the group's best member (Hill, 1982, cited in Salazar, 1995). Pavitt and Curtis (1994) noted that the "best member" model of team problem solving suggested that the odds that a group will find the correct solution are the same as the odds it contains a competent group member.

"Assembly effect bonus" is a group process outcome documented in a few studies. It suggests that the group is able to do something that could not have been achieved by any member working alone or by a combination of individual efforts. Although there is scant research evidence for "assembly effect bonus," the idea is appealing and may underlie the trend in collaborative, team problem solving in schools.

Likewise, groups have made decisions that were less than what could be achieved by its best member (Libby, Trotman, & Zimmer, 1987). This has been termed "process loss." It is attributed to faulty group interactions, resulting in poor decision making. For example, group problem solving can result in members merely confirming the commitment to one another's present practice. Process loss may be avoided by improving group interactions.

Based on their work in over 60 schools in four states, Rosenfield and Gravois (1996) found broad participation team problem solving of individual referrals to be an impediment to addressing classroom teacher concerns in a timely fashion. They changed the tasks of team meetings to an emphasis on systems-level problem solving. Ongoing training of members, monitoring and documentation of case outcomes, and ensuring that systems interventions were implemented in ways that served the needs of all children became the team focus.

Teams assigned individual referrals to members on the basis of skills and interests. The assigned team member became the case manager and employed systematic problem solving with the teacher and parent(s). This practice is in alignment with the "best member" model of team problem solving.

In summary, it would be a mistake for school psychologists to have unconditional and non-reflective enthusiasm for broad participation team problem solving. It is possible, however, for school psychologists to base team practices on findings from the following bodies of literature: (a) teacher reports of satisfaction with specific team processes and team effectiveness (e.g., Aksamit & Rankin, 1993; Chalfant & VanDusenPysh, 1989), (b) efficacy results noted in studies of the explicit problem-solving processes of behavioral and conjoint behavioral consultation (e.g., Elliott & Sheridan, 1992), and (c) the extensive literature on school and organizational change (e.g., Fullan, 1991).

RESOURCES OF TEAMS

Despite the popular notion that team members are collaborative generalists, the emphasis in this section is on recognition of expertise as an important resource. "Practitioners as generalists" stemmed from problem solving research of the 1970s. The focus was on general strategies or abilities needed to solve problems and the role of experience was downplayed.

In the 1980s, research in computer assisted diagnosis, consultation, expert systems, and artificial intelligence clarified the need for an extensive knowledge base and experience to solve problems. Novices do not become experts overnight. The development of expertise is very complex. Becoming truly expert is about a 10-year process of deliberate practice. Accordingly, research in problem solving has shifted from a focus on general strategies of reasoning to the structure of expert knowledge.

Expert and novice problem solvers tend to be alike in their knowledge of strategies, depth of processing, and number of alternative routes they explore (Elstein, Shulman, & Sprafka, 1990). The differences are that experts linger on the identification and definition of the problem, thereby enhancing the probability that the solution will be a quality one. Experts also seem to have definite ideas about what data would be necessary to solve the problem and are more selective about the data they collect than are novices. Experts explore better alternatives because of differences in their structure of knowledge rather than differences in knowledge of strategies. This suggests that persons with the most expertise in the referral or target problem and in data collection should take the lead role in collaborating with teachers and parents to define the problem, develop the data collection plan, and select the intervention(s).

Being an expert in test and place forms of problem solving is likely to interfere with learning problem solving for interventions due to the inhibitory effects of early learning on acquisition of new material (Bruning, Schraw, & Ronning, 1999). An early and important example of this is functional fixedness, loss of the ability to view the familiar in a novel way (Duncker, 1945). New content and processes can be learned, but learners must commit themselves to a steady regimen of practice and feedback that includes supervision by highly skilled mentors.

Research findings provide some criteria for determining who are the experts. The use of peer nominations to select experts has been discarded for the most part. Peers tend to know little about the expertise of their colleagues and make their selections on the basis of whom they trust. Years of experience, specialty certification, and occasionally rank or responsibility have become the accepted indicators of expertise.

A combination of less experienced and more experienced team members potentially could be a wise selection. Less experienced team members, when recent graduates of institutions of higher education, may be informed about the process of problem solving for interventions. More experienced team members, on the other hand, may have expert knowledge structures helpful in data collection and exploration of better solutions. Respecting members' differing areas of expertise facilitates team functioning.

All team members have their own particular areas of expertise from which to draw throughout the problem-solving process. One example is that parents know their child best, hold an important vision for their child, and are the child's strongest advocates. Parents are experts on what has worked for their child in the past and what the family can do to support new interventions.

BASIC CONSIDERATIONS

Team structure and process skills are an insufficient foundation for developing interventions in PST meetings. School psychologists may need to be open to changing their beliefs in order to change their practices. Beliefs about how the world is and should be drive the questions, define the tasks, and guide the decisions of team members. School psychologists also need to develop competencies in behavioral consultation, conjoint behavioral consultation, assessment techniques that link directly to research-based interventions, and measurement for progress monitoring.

When team members do not have explicit education and practice in problem-solving processes, communication during meetings may resemble Stack's (1997) findings. She analyzed communication units from problem-solving meetings in which team members were attempting to change from processing referred students for special education placement to processing for intervention design.

Although systematic problem solving appeared in the teams' documentation, communication resembled traditional test and place dialogues. Most of the members' communication units centered on identifying the problem (66%) with little or no time spent in the other areas (i.e., define, apply solutions, look back, and evaluate). Many units that identified the problem referred to characteristics within the child or the child's home environment. Dialogues of three cases that show team members continuing to work from the decision frame of pathology within the child and/or family needing diagnosis (e.g., Does the child have a disability?) are in Table 1. The outcome for each child was special education placement (e.g., Does the child qualify for special education?).

In problem solving for intervention, the dialogue at problem identification and definition sounds more like the following, using case 1 from Table 1 as an example. The emphasis is on what Joey can do in reading, the instruction he has received, and the outcomes of the instruction. The communication units move the process toward brainstorming interventions and away from communication about IQ-achievement discrepancies that lead to diagnosis and placement.

Teacher: "Joey has difficulty with reading."

Team facilitator: "Tell me more about it" or "What can Joey do well in reading?"

Teacher: "He tries to sound out every word. He can do it but it slows him way down and everyone is sitting there waiting on him. He is r-e-a-l-l-y slow."

Team facilitator: "You see Joey relying on sounding out words as a major reading strategy. What additional reading strategies do you see Joey use?"

653

Table 1. Communication units for teams learning to problem solve for interventions

Case 1

"Joey has difficulty with reading…He is the lowest reader in my group…He is r-e-a-l-l-y slow…He will be 7 on March 18…I think his I.Q. is a little lower…Yes, I think his ability is low…What are his MRT scores?"

Case 2

"Sandra has no concept of numbers, letters, subtraction…She missed a lot of school…She is very eager to please, but I have a feeling the problem could be coming from home…I think Mom spends a lot more time with the older sister…Mom has a short fuse."

Case 3

The teacher began by saying, "This is an academic concern…I don't see any developmental problems."
Team member asked, "Socially is Susan doing ok?"
Teacher, "Well, her behavior is going downhill rapidly."
Team member asks, "Is it seizures? Is it true LD?"
School psychologist replies, "If it were LD, we wouldn't be identifying it in kindergarten."
Teacher, "The parents move frequently."
Nurse, "Have we tried an ACTrS?"

Teacher: "Nothing else. If he can't sound it out, he eventually just quits and sits there. He is the lowest reader in the group."

Team facilitator: "What instruction in additional strategies has Joey received? What have you tried so far?"

Teacher: "I tell them all to skip unknown words, read ahead, and decide what makes sense. But Joey doesn't know enough words to benefit from that. He doesn't even know all the basic sight words. We started working on those but I don't have enough time…"

The above dialogue yielded information that could be used for brainstorming interventions that the regular classroom teacher and home could collaboratively implement (e.g., Word Wall, flash cards, selection of books in which Joey has prior knowledge/vocabulary/high interest).

In case 2, the communication process skills illustrated later in the chapter would be helpful. For example, the teacher began with math concerns. Someone in the group turned the focus to home problems. Given what was said about Sandra's mother, the home was not represented at the problem-solving table. The skill of refocusing needed to be used. It might sound like this:

Team facilitator: We have two separate issues on the table. The referral concern is academic, specifically difficulty with number and letter concepts. The second issue is questioning whether there are home difficulties. Let us concentrate for now on the academic concerns that we can define and invite Sandra's mother to collaborate in helping her daughter.

Stack further described her observations of problem-solving meetings as multiple conversations occurring at the same time and loosing sight of the children and their needs while conversing about possible pathologies and rules and regulations. Teachers consistently expressed helplessness and frustration with the new process. They openly stated that it was a waste of time, a new administrative hoop to jump through to place students in special education programs.

Without basic competencies for not only school psychologists but also other team members, communication will continue to sound like engagement in a "test and place" process. Paperwork might look like problem solving for intervention design but process will not.

BEST PRACTICES

Based on student outcome data, there is clearly more empirical evidence to support the use of specialist teams than the use of broad participation teams in the problem-solving process. Broad participation teams abound and anecdotes suggest that some are successful. As a general rule, the more people on the team, the more critical group process skills become. The less expertise that team members have in problem solving for interventions, the more critical group process skills become. Regardless of the type of teams in their schools, school psychologists are encouraged to assist them with the necessary structure and process.

Team Structure

TIME FACTORS

Notably, time factors are the most frequently cited problem area both for elementary and secondary PSTs that are composed of broad participation. In fact, administrators have identified teachers' willingness to put in extra time and effort as a major factor contributing to effective teams (Aksamit & Rankin, 1993). School psychologists can help foster beliefs that it is normal and expected to do more and different things for referred students.

Finding meeting times, meetings taking too much time, and lack of time to accomplish all that is required in problem-solving meetings are specific areas of concern (Aksamit & Rankin, 1993). It is recommended that teams select a specific time of the week to meet and allow nothing to interfere with it. Teams that meet on a regular basis, and at a specific time, more quickly become an accepted part of the school culture.

In addition to setting a specific time, it is important to set an adequate length of time for team meetings. Team decision making has been shown to be adversely affected by time constraints. Specifically, PST members said lack of sufficient time to problem solve and make decisions was their most frequent concern. The quality of their decisions was impaired by the apparent need to rush through cases in order to stay on schedule. This is less of a problem when a given meeting time is devoted to processing one referral.

Teams are made aware of the passing of time when they appoint members to the role of timekeeper. This can assist team members in knowing when to use group facilitation skills of refocusing and limit setting. Timekeepers help teams complete the step of generating and selecting solutions before teachers or parents must leave for other commitments.

MEETING PREPARATION FACTORS

Teams function within the established time limits when members come prepared. For broad participation teams, it can be useful to appoint a consultant/case manager prior to the first problem-solving meeting of any given referral. The case manager can document the referral reason, review records, assist the teacher in bringing helpful information to the meeting, and interview the parents. Case managers summarize preliminary findings in written memos provided to team members prior to the meeting. Premeeting efforts can greatly reduce the amount of meeting time spent on the first step of problem solving, identifying the problem. The team can move more quickly into defining the problem, followed by brainstorming solutions, and designing the plan.

MAKING THE PURPOSE OF THE MEETING EXPLICIT

Effective decision-making practices consist of several components. First, the purpose of the meeting must be made explicit. This might not seem like a big revelation, but research has shown that the purpose of meetings was seldom explicitly stated (Ysseldyke, 1983). Begin each meeting by explicitly stating the purpose for meeting and clarifying the steps of problem solving. Introduce the steps in both oral and written form at the beginning of problem-solving meetings. Explicitly point out each step as the team engages in it.

Provide members with copies of the interview questions that will be asked during problem identification, problem definition, and each subsequent phase of problem solving. Appropriate questions are found in conjoint behavioral consultation or behavioral consultation (Kratochwill & Bergan, 1990) and instructional consultation literature (Rosenfield & Gravois, 1996). Remind members that the referral sources (e.g., teacher and parents) will be asked for their input first.

TEAM STRUCTURE: CASE MANAGEMENT MODEL

Team structure developed and implemented by Rosenfield and Gravois (1996) is notably different from broad participation team structures. They recommend using teams that consist of the school psychologist, guidance counselor, one or two administrators, reading teacher, one to three special education teachers, two to five general education teachers, and as many as four additional educators. The team meets face-to-face on a frequent basis. There is a focus on the development of group process skills and positive interdependence. All members receive ongoing training in case management (e.g., consultation, intervention design, progress monitoring). Members hold one another accountable for individually assigned responsibilities and engage in regular assessment of team functioning. Systems level needs are discerned based on referral patterns and team members facilitate systems change accordingly.

Referrals are made to the team leader/facilitator. At team meetings, members determine who to assign as case managers on the basis of skills and interests. Teachers on the team are assigned no more than one or two cases at a time; other team members often can be assigned more than two cases. Case managers become consultants who bring parents and teachers together for problem solving. This constellation forms a small team of the following three to four people: consultant, referring teacher, and parent(s). Conjoint behavioral consultation is a made-to-order match for this team structure.

TEAM STRUCTURE: BROAD PARTICIPATION MODEL

In contrast, broad participation team problem solving requires all team members to meet with parents and teacher(s). At initial levels of referral, prior to consideration for entitlement to special education, members consist of building level personnel (e.g., principal, general education teachers). A typical constellation of group members is the building principal and/or the building director of support services, guidance counselor, general education teacher(s), special education teacher, and parent(s) of the referred child. These group members tend to meet once a week at a regular time. They may process from one to several cases at each meeting. It is rare that any one individual member is assigned to work with parents and teachers. Support personnel (e.g., school psychologists, social workers, speech and language clinicians) usually are not involved at the initial levels of problem solving. They become involved when the assistance team wants help in designing more successful interventions.

ROLES AND EXPECTATIONS OF TEAM MEMBERS

One of the primary objectives of teams is to effectively use the resources of each individual member. When team members feel their area of expertise is infringed upon, they view team collaboration as a surrender of power and influence. As a result, they develop negative attitudes toward PST members and team decision making. Inter-professional tension can become a powerful inhibitory barrier to successful team functioning.

Wynn and Guditus (1984) found that teachers showed a strong preference to be involved in decisions directly related to their work in classrooms. Participation in the group process was related to satisfaction with decisions and commitment to implementing them. School personnel also gave more favorable ratings to teams that possessed the highest degree of collaboration.

One solution is to assign members to roles that use their interpersonal and professional strengths and provide them with explicit oral and written role expectations. Typical roles are leader, time keeper, recorder, case manager, and member. The role of parent advocate is not assigned typically. It is a critical role that can better use team resources to enhance outcomes (Brown, Pryzwansky, & Schulte, 2001).

Groups may be dominated by one or a select few members with strong personalities who may persuade the remaining members to accept underdeveloped solutions or inadequate recommendations. More powerful members must recognize their authoritative position and strive to work with others to redistribute power. School psychologists and special educators provide a disproportionately larger input when compared to other members of the PST. Classroom teachers and families are less active participants. This has led to less satisfaction with team decisions and little internalization of the team's proposed educational plan by the people most responsible for implementing it.

Explicit knowledge of roles and expectations can help mediate power imbalances. An additional strategy is to structure communication so that members contribute in an organized manner. Teacher and parents are asked to contribute first and are provided ample prompts and support. Additional members are called upon to contribute later. In summary, plans will be implemented when all PST members are actively participating. This is true whether the plan is a single intervention, a modification for a classroom, a program change, or the restructuring of an entire service delivery system.

Group Process

Researchers have suggested one of the underpinnings of quality PSTs is systematic decision making. Yet PSTs in education have been criticized for their loosely structured and nonsystematic decision-making processes. Skill deficits in obtaining, organizing, and presenting information can doom decision making to failure.

Local education personnel most likely to have skills in group process are guidance counselors, special education teachers, and school nurses. Typically, principals and regular education teachers do not have training in group process skills. However, they may have developed group process skills or have an interest in developing skills and should not be overlooked as possible team leaders. Research reports of who leads problem-solving assistance teams vary from coordinators and teachers at the elementary level to support personnel and teachers at the secondary level (Aksamit & Rankin, 1993). Support services personnel such as school psychologists, social workers, and educational consultants may have group process skills and be able to train others.

FACILITATING GROUP COMMUNICATION

Facilitation is an important process skill. A common dictionary definition of facilitate reads "to make easy or easier." For a group leader to facilitate means to assist, encourage, foster, and support group members in order to make it easier for them to participate successfully in the group. Any group member with process skills can assist the group in constructive processing, also. In the following example, Kyle is the group leader, and he uses several small group process skills to help group members communicate and participate, build trust, and help the group make difficult decisions. Note that Julie, who was not the leader but a member, helped the group by using the process skill of refocusing.

Kyle is leading the assistance team in a problem-solving meeting. Kyle set the tone for the team's task by directing everyone's attention to the list of problem-solving steps posted on the wall of the meeting room. He provided brief and explicit descriptions of the steps and then stated the purpose of the meeting.

Throughout the meeting, the team challenged him in several ways to pay close attention and help them process effectively. Kim always had a lot to say. She would have talked non-stop if Kyle had not interrupted, thanked her for her contribution, and asked the parent and the teacher, respectively, questions to help define the problem. There was a tense moment when Willie and Clare began debating about the reasons the referred student was having difficulty. Their discussion would have escalated and taken over the rest of the meeting if Julie had not refocused the conversation. The observations Clare shared were helpful in defining the target problem of the referred student. Julie summarized what she had said and asked others what they had observed. During brainstorming of solutions, Kyle noticed that Julie was unusually quiet. He made a point of inviting her to participate. After brainstorming, Kyle led the team in the process of deciding exactly what they would do in the next few weeks.

Effective group leaders and members keep a pulse on communication in the group. One way they do this is by periodically asking themselves questions such as:

- *Are the major stakeholders (e.g., teacher, parent) encouraged to be active participants?*

- *Is everyone getting a chance to speak?*

- *Are the speakers' messages appropriate to the current problem solving stage in which the team is engaged?*

- *Are there any topics the group is avoiding?*

This chapter cannot provide a detailed account of all skills necessary for effective group leadership. However, basic, foundational, group process skills are described below. Examples of what to say and when to say it are included in Tables 2–5.

LISTENING

Facilitating effective group communication through listening is the first skill set and can be found in Table 2. At the foundation are the active listening techniques; that is, listening both for the facts and beyond the facts for feelings, attitudes, assumptions, and beliefs. Many school psychologists learned these basic techniques in counseling courses. Listening techniques, used effectively in group settings, let speakers know they are being heard, understood, and encouraged to say more.

Asking for clarification includes asking group members to give reasons for what they have said, encouraging group members to think through what they are saying, and encouraging the expression of wide-ranging and well-thought-out opinions. Seeking clarity is a critical communication skill to use

Table 2. Facilitating effective group communication

Skill	*When you use this skill, you:*	*Examples of what to say*
Active listening	*Clarify:* Ask for information.	Tell me more about that. Then what happened?
	Reflect: Say back the content, feelings, attitudes, or opinions you heard.	It seems that you feel... Your perspective is...
	Encourage: Assure the speaker you would like to hear more.	When we develop our strategy, please tell us more about what your experiences were.
	Summarize: Sum up what was said.	Let me make sure I understand everything...
	Explore implications: What does the speaker think this means?	What do you think about that? How do you think this will affect...?
Seeking clarity	Use open-ended questions that can't be answered with "yes" or "no."	How do you... What do you think about...
	Ask someone to clarify her/his comment.	He tantrums? What does he do?
	Ask others to express their thoughts on a comment someone else made.	Diane wonders if the tantrums are to avoid doing work. What do the rest of you think?

Table 3. Encouraging group participation

Skill	*When you use this skill, you:*	*Examples of what to say*
Including	Provide opportunities for members to participate with a minimum of risk; request, but don't force, involvement.	Let's hear everyone's experience with the tantrums. If you don't have anything to share, you can pass.
	Acknowledge quieter individuals' comments to build their confidence, but don't overdo it and embarrass them.	Thanks for sharing that. That helps me understand where you're coming from.
Affirming	Openly thank a group member for a comment, and say why you're expressing your thanks.	Thank you for telling us about his alcoholism. It may change what we do. Thanks, Pat, for sharing what you do to help him calm down. Now we can try those things, too.
	Make a positive observation about what a group member says.	What a positive way to view it! I can tell you've thought carefully about that. I appreciate your trusting us enough to say that.
	Agree with what someone says.	I have noticed that before, too.
Extending	Draw attention to a member's comment to get a discussion going or to draw others into discussion.	That's a creative approach to this situation. What do others think about that? Thanks for that observation, Nancy. Does that bring a new idea to mind for anyone else? That's important information about this intervention. Has anyone else read or heard of something we should consider in our intervention design?

(Table continues on the following page.)

Table 3. (continued)

Skill	*When you use this skill, you:*	*Examples of what to say*
Refocusing	Point out that the group has gotten side-tracked.	We've gotten off the track a bit. Let's get back to step 2, defining the problem. Mary, what do you do when Janell is drawing instead of writing?
	Give an alternative to continuing the discussion now.	I can tell this is really important to several of us. Let's take some time to think about it this week. It will be on the agenda of the next meeting. Let's get back to…
	End or postpone the discussion or bring it back within appropriate limits.	You know, this issue is something that needs to be dealt with by those directly involved. Let's table our discussion of it until they can participate. What we can discuss right now is…
Limit setting	Assertively manage the behavior of individuals in the group when necessary, for example, with those who monopolize discussion. Matter of factly direct the actions of the entire group when necessary.	Jan, let's hear some other people's ideas on that. Mark, I want to make sure everyone has time to share. Let's get started. Let's get back to the subject. We've spent all the time we can on that.
Intervening	Call attention to something that has hurt someone's feelings.	Some things have been said here that might have hurt John's feelings. It is important that we are respectful at all times. John, how are you doing?
	Point out a dynamic in the group that is not in the group's best interest.	It seems to me that whenever someone talks about a problem, the rest of the group wants to fix it right away. Let's wait until after brainstorming all possible solutions…
	Help group members resolve a conflict.	Our discussion has turned into a disagreement. Let's take some time to find a solution that helps us work together collaboratively.

Table 4. Building trust and group cohesion

Skill	*When you use this skill, you:*	*Examples of what to say*
Self disclosure	Share from your life experiences to let group members know that you, like they, are not perfect.	Now here is something I've always had to struggle with. This is really difficult for me to talk about because… When something like that happens to me, I feel so inadequate. I sure blew it once when I…

Table 5. Group decision making

Skill	*When you use this skill, you:*	*Examples of what to say*
Brainstorming	Explain the rules.	Anything goes… Write the ideas on a chalkboard or easel.
	Solicit ideas as fast as they come from whoever has them or round robin.	Let's proceed around the table. Say pass if you don't have an idea when it is your turn.

(Table continues on the following page.)

659

Table 5. (continued)

Skill	*When you use this skill, you:*	*Examples of what to say*
Sorting down	Give each group member a certain number of votes.	Vote for your top two picks.
	Take a show of hands on each item.	Raise your hand if student choices is one of your top picks.
	Sort the list down to items that received the most votes.	Four or more votes went to give choices and provide picture cues.
	Repeat the process if you still need to reduce the total number of ideas.	

throughout problem solving, particularly during the problem definition stage but also during subsequent stages. See Table 2 for examples of different uses of this skill and what to say.

ENCOURAGING GROUP PARTICIPATION

Effective group leaders and members make sure each group member has a chance to participate. Leaders not only encourage quieter group members to get more involved, but also keep more active members. from taking over. Table 3 lists including, affirming, extending, refocusing, limit setting, and intervening as skills used to encourage balanced and task appropriate participation by the various group members.

Including techniques help members draw more reluctant or quieter participants into discussions and sharing. Quieter members are often parents and teachers, the very members that need to be active participants. When affirming, respond positively to group members as they participate in group activities. Members need to be on the lookout to affirm each person in the group, including quieter individuals.

Extending is a way to get the most out of group members' comments during a discussion. It invites others in the group to share their thoughts on the same topic. Members must be careful to use extending appropriately because team members often report that there is insufficient time for quality problem solving. See Table 3 for examples of the use of extending.

Refocusing means getting a discussion back on track, ending a discussion, or keeping a discussion appropriate. This group process skill may need to be used often when team members are first learning how to problem solve for intervention design. If a team member thinks she cannot be assertive in refocusing group discussion, then she may not want to volunteer for the role of team leader. Table 3 provides examples of refocusing.

Gently letting the group know that it is time to stop something is limit setting. See Table 3 for examples of how it provides the opportunity for others to participate in the group. This is another facilitation skill that may feel too assertive to some members. They may determine that they do not want the role of team leader.

Intervening is stronger than limit setting. Use this skill on the rare occasions it is needed. Intervening means doing whatever has to be done to stop potentially destructive behaviors, such as ganging up on one group member, breaking confidentiality, bullying a group member, or being insensitive to others' feelings. Use as little force as necessary to end a destructive behavior, but make sure it stops. See Table 3 for examples.

BUILDING TRUST AND GROUP COHESION

Groups' cohesiveness increases in proportion to the trust its members feel in one another. Group leaders can use a variety of techniques to offer ongoing opportunities to group members to build and maintain trust. Most techniques rely on the skill of disclosure, shown in Table 4. Disclosure involves sharing one's thoughts, feelings, and experiences. Modeling self disclosure is a way of teaching group members about this important tool for building relationships.

GROUP DECISION MAKING

From a group's first meeting to its final stages of maturity, group members need to know how to make decisions. Decisions can range from the very simple to the challenging. There are three steps that are useful in many different decision-making situations.

Brainstorming is a creative way to come up with more than one right answer. See Table 5. The rules for this technique are the following: Anything goes. All ideas are welcome. It is okay to piggyback on someone else's idea. The wilder the ideas are, the better. No negative comments, criticisms, or evaluations are allowed—just ideas.

After brainstorming the facilitator helps the group sort down (see Table 5). This involves deciding which of the brainstormed ideas merit serious consideration. The facilitator gives each member input as the group progresses toward a decision and enables each member to see the process clearly as it unfolds. To reach a final decision, the group may use gaining consensus.

Consensus involves enabling a group to reach a decision that all can accept. Tell what the options are, after brainstorming, or when the solutions have been sorted down to a couple of options. If there is disagreement, then ask each group member to share his or her thoughts, ideas, or feelings, or simply invite comments from the group. If the group reaches impasse, then try one of the ideas for a while, then evaluate it, or come up with a compromise. Avoid pressuring individuals into a solution with which they're not comfortable. The major implementors of the solution typically are the parents and teachers. They must be comfortable with the final solution.

TECHNIQUES TO AVOID IN LEADING GROUPS

The following techniques get in the way of group leaders' and members' effective communication and group growth: (a) ordering, directing, commanding; (b) warning, admonishing, threatening; (c) exhorting, preaching, moralizing; (d) giving solutions; (e) judging, criticizing, blaming; (f) name calling, ridiculing, shaming; and (g) interpreting, diagnosing, psychoanalyzing. Guard against them and be on the alert for them in other group members. Most people have used these techniques before, and it is easy to slip into using them again, especially in tense situations or when not feeling confident.

The group process skills described here are critical to effective systematic decision-making processes of team problem solving for interventions. Many school psychologists have developed some basic process skills through education and experience in counseling. If so, they will have little difficulty generalizing their use to team problem solving meetings and learning additional process skills.

SUMMARY

Many team members experience frustration, feelings of inadequacy, and failure in their attempts to change group processes from focusing on diagnosis and placement to focusing on general education interventions. School psychologists have an important role to play in helping teams develop processes that facilitate the transition. To assume the role, many school psychologists need to develop various competencies themselves. A place to begin is refining one's team structure and process skills. Effective structure and process have the power to facilitate group cohesiveness, encourage participation, and improve communication when attempting to transform the tasks and goals of team meetings.

Best Practices in Using Curriculum-Based Measurement in a Problem-Solving Model

Mark R. Shinn
University of Oregon

OVERVIEW

Curriculum-Based Measurement (CBM) is a set of standardized and validated short duration tests that are used by special education and general education teachers for the purpose of evaluating the effects of their instructional programs (Deno, 1985, 1986; Fuchs & Deno, 1991)in the basic skills of reading, mathematics computation, spelling, and written expression (Deno, 1985, 1986, 1989; Shinn, 1989b, 1998). CBM is not a tool to be used on a daily basis by school psychologists as part of their assessment activities.

In an earlier edition of *Best Practices* (Thomas & Grimes, 1995) I asked this question: Given that the principal use of CBM is by teachers to assess student achievement outcomes on an ongoing basis, a logical question arises. Why should *school psychologists* be interested in CBM?

At that time I offered reasons that were divided into two broad categories: concerns about (a) programs and services for students with disabilities and (b) the educational and psychological needs of *all* children. These concerns have not only not diminished, their importance has increased in visibility in educational practice, policy, and law. This chapter provides a rationale for why school psychologists and other educators should be interested in the use of CBM, especially within a particular decision-making model, Problem Solving (Deno, 1989, 1995). The chapter concludes with an example of how CBM is used in Problem Solving via a case study.

Special Education Concerns

In my Best Practices III chapter, I saw three major concerns related to school psychology practice that served as compelling reasons why school psychologists should be interested in CBM and its use in a Problem-Solving model: (a) ineffective special education programs, (b) the lack of quality Individual Education Plan (IEP) goals and objectives, and (c) the misalignment of assessment and intervention. I see these issues as highly related, beginning with the last and working backward. Briefly, because prevailing special education assessment practice generates information that may be useful for eligibility, but that is not instructionally relevant for writing quality goals, poor IEP goals are written. Because poor (e.g., hard to measure, of limited instructional utility) IEP goals are written, progress is not monitored systematically by teachers. Consequently, ineffective interventions are not modified resulting in lower than expected achievement by students with disabilities.

LACK OF SPECIAL EDUCATION EFFECTIVENESS

School psychologists have had a long-standing concern about the effectiveness of special education. More than a decade ago, a survey by Reschly, Genshaft, and Binder (1987) provided evidence of a striking discrepancy between the major activity of school psychologists, testing students for special education eligibility (Hutton, Dubes, & Muir, 1992; Smith, 1984), and their feelings about a lack of positive outcomes generated by these services. Only about one-third (32%) of responding practitioners agreed with the statement that special education services are usually "quite effective."

These professional opinions are echoed by every meta-analysis of special education effectiveness since 1980 (Carlberg & Kavale, 1980; Forness & Kavale, 1987; Kavale & Forness, 1985, 1987). Most recently, Kavale and Forness (1999) stated that

> Most (special education interventions) revealed an ES (effect size) below .5 and thus represent less advantage than one-half year's worth of schooling.... The special education interventions demonstrated effects that primarily ranged from negligible to small, and at best, *medium* (their emphasis) (p. 1003).

Results from meta-analyses are echoed in concerns from major national task forces such as the National Agenda to Improve Outcomes for Persons with Disabilities (U.S. Department of Education, 1994) and individual studies of special education practices. For example, Vaughn, Moody, and Schumm (1998), in a powerful study entitled "Broken promises: Reading instruction in the resource room," confirmed what many earlier studies had documented: that special education instruction was not notably different from that delivered in general education classrooms. Vaughn et al. (1998) reported teachers in special education using the same grouping practices and instructional materials as their general education counterparts and "provided little differentiated instruction" (p. 221).

IEP GOALS AND OBJECTIVES

Another concern tied to the lack of special education outcomes is the quality of special education students' IEP goals and objectives. Without quality goals and objectives, evaluation of individual student's outcomes is problematic, and, as a result, ineffective interventions will not be identified and modified. Special education legislation (e.g., the Individual Disabilities Education Act) has long recognized the needs for evaluation of individual program outcomes and mandated that each student with a disability have a statement as to what the special education intervention is designed to accomplish on at least an annual basis. However, nearly two decades after implementation of the original Education for All Handicapped Children's Act (1975), the quality of IEPs has not improved significantly (Bateman & Linden, 1998; Smith, 1990). For more detail, see Shinn and Shinn (2000).

Typically, IEP goals are written without current student performance data, are vague and lack observable, measurable outcomes (e.g., "Will improve 1 year in reading"), or present lists of isolated short-term instructional objectives (e.g., will master C-V-C words with 80% accuracy). Compounding the problem of difficult-to-measure goals is the lack of consensus as to what student goals should be. Too often, special education goals are procedurally driven (e.g., dictated by "district policy") as opposed to a meaningful discussion as to what an individual's special education program is designed to accomplish.

LINKING ASSESSMENT AND INTERVENTION

The third major special education concern for school psychologists is the lack of treatment validity of their assessment data. Information collected most often comes from published norm-referenced tests of aptitude and achievement (PNTs). Extensive discussion as to the limited treatment utility of PNTs is beyond the scope of this chapter. The reader is encouraged to see Marston (1989) or Howell and Nolet (1999) for a more extensive discussion of this topic. In brief, although many PNTs are well constructed as *global* measures of general abilities (e.g., reading), the very nature of their broad-band content precludes their usefulness for goal setting and intervention planning. The tests' limited number of items are spread across too large an age span and too few are tied to specific curriculum. These problems lead to questionable conclusions about what a student does or does not do correctly and what a student needs to learn to be successful in a *specific* general classroom curriculum. Additionally, PNTs rely almost exclusively on selection-type response formats (e.g., pointing to one of four choices) that are not "authentic." These types of responses provide information only on correctness, not on what strategies or preskills a student brings to bear on a task (Howell & Nolet, 1999).

Remedies in IDEA 97 and the Linkage to CBM to Redress These Concerns

As discussed in more detail in Shinn and Shinn (2000), Congress set forth to remedy these three

661

issues, among others, in the revision of the Individuals with Disabilities Education Act of 1997 (IDEA 97). Explicitly stated within the revision was the need to (a) assess educational need; (b) write measurable annual IEP goals, monitor progress, and report progress to parents at least as often as progress is reported about non-disabled students; and (c) make revisions in the IEP to address any unexpected lack of progress. The critical component in each of the explicit statements is the need to make these decisions and actions in the context of participation and progress in *general curriculum*.

The ability of CBM to help accomplish the intents of IDEA 97 is one of the reasons that it should be of interest to school psychologists and educators alike. The use of CBM is advantageous in that the source of its testing materials is general curriculum. The linkage from what is tested to determine educational need and special education eligibility to IEP goal setting and progress monitoring and IEP revision is direct and requires fewer inferences than conventional assessment practices. CBM measures are "narrow band" in general curriculum test content as its test items typically encompass only 1 year of a curriculum for each level of the test. *All* items are derived from the curriculum used in general education classrooms, and thus maximize testing/teaching overlap. Finally, CBM relies on production-type, authentic response modes. Students read aloud from text, write dictated spelling words, write answers to mathematics computational problems, and write stories. These types of responses allow information to be gained not only about correctness, but *how* and *why* students answered in specific ways.

A clear advantage of using CBM with students with disabilities is that it is a technology that has been *validated* for use in writing observable and measurable IEP goals and making statements about progress in general curriculum (Fuchs & Shinn, 1989; Shinn & Shinn, 2000). In fact, CBM's research-based development was supported by federal funds to identify a technology to assist in implementation of the original Education for All Handicapped Children Act, P.L. 94-142 (1975). For more detail on this history, see Deno (1992) or Shinn and Bamonto (1998).

When CBM is used to write IEP annual goals in general curriculum, students with disabilities' achievement outcomes improve. Numerous studies by L. Fuchs and D. Fuchs (e.g., Fuchs, 1998; Fuchs, Deno, & Mirkin, 1984; Fuchs, Fuchs, & Hamlett, 1989; Fuchs, Fuchs, Hamlett, & Allinder, 1991; Fuchs, Fuchs, Hamlett, & Ferguson, 1992; Fuchs, Fuchs, Hamlett, & Stecker, 1991) have shown that when teachers use CBM to write data-based goals, monitor the effects of their instructional programs, and adjust their interventions when the data show little outcome, student achievement improves. Typical effect sizes, the amount of standard deviation gains in achievement attained by members of the treatment group versus controls, exceed .5 (Shinn & Hubbard, 1992). Because school psychologists are concerned about the limited or negligible effects of special education and use of CBM is not only consistent with the changes required by IDEA 97 but also improves achievement outcomes, they should be interested in implementing CBM.

Educational Needs of All Children

School psychologists are becoming increasingly aware of the need for *prevention* as a major practice activity. However, they remain burdened by their heavy time commitment to testing for special education eligibility. CBM can help school psychologists contribute to meeting the needs of *all* children directly and indirectly (Tilly & Grimes, 1998).

Direct contributions of CBM are evidenced by reducing the need for school psychologists' mandatory and extensive participation in special education eligibility testing. When CBM is implemented in a Problem-Solving model, school psychology testing for special education eligibility is reduced significantly and corresponding increases in intervention services to all children are noted. Such changes were reported by Canter (1991) in Minneapolis Public Schools and as part of statewide special education reform in Iowa (Tilly & Grimes, 1998). Rather than routinely testing every referral for purposes of determining special education eligibility, when CBM is used in a Problem-Solving model, school psychologists test students only when there are specific assessment questions. Because special education services are provided when educational need is demonstrated and initial problem-solving interventions fail, the use of ability tests is reduced or eliminated. For more detail, see Tilly, Reschly, and Grimes (1999).

With a decrease in eligibility testing, increases in school psychologists' intervention activities are observed. For example, in Minneapolis, consultation to general education and special education teachers increased from 12% to 36% of cases within 3 years; within 5 years, this figure increased further to 52% of cases (Canter, 1991). Similar changes in the intervention activities of school psychologists are noted in the Heartland Area Education Agency in Iowa (Ikdea et al., in press).

Indirect contributions of CBM occur when it is used in general education classrooms as part of standard promotion and prevention practices. This use is increasing in occurrence where general education teachers administer CBM probes to all students at the beginning of the year as part of an initial assessment. This information is used to identify at-risk students for immediate problem-solving activities rather than waiting for problems to intensify. General education teachers also use this information for instructional planning, including evaluating text difficulty and instructional grouping, and as an initial data point for evaluating progress. All students subsequently are retested by using either (a) a *Benchmark Testing* approach where progress is evaluated quarterly or every trimester or (b) a *Strategic Monitoring* approach where progress is evaluated monthly. This proactive use of CBM allows school psychologists to be active in assisting general education design environments that result in positive outcomes. For example, should the progress of large numbers of students be insufficient, school psychologists may contribute to decisions about curriculum choices. This proactive use also creates opportunities for school psychologists to be involved in general education problem-solving and instructional-planning decisions with individual students. For more information on the use of CBM in promotion and prevention in general education classrooms, see Shinn, Shinn, Hamilton, and Clarke (in press).

BASIC CONSIDERATIONS

Given these compelling reasons for school psychologists to be interested in CBM, then the question becomes, *Just what is CBM?* This question is important to answer because practitioners have encountered a virtual explosion of information in the professional literature on a wide range of testing strategies that collectively can be called *curriculum-based assessment* (CBA). Among the numerous assessment techniques considered CBA are informal reading inventories, end-of-unit mastery tests, analysis of homework samples, performance assessments, precision teaching, and a variety of locally made tests that measure what students are learning. To reduce confusion, it is important for practitioners to discriminate the similarities and differences among the variety of approaches collectively entitled CBA. For more information on this topic, the reader is referred to Shinn, Rosenfield, and Knutson (1989), Shinn and Bamonto (1998), or Tindal (1993).

In brief, CBA is a very broad term that describes *any* testing strategy that uses a student's curriculum as the basis for decision making. CBM is a particular *type* of CBA. Testing is accomplished by using a limited number of standardized and validated measures of student performance in the basic skill areas of reading, spelling, mathematics computation, and written expression. Specifically, CBM measures consist of the following core testing strategies:

1. In reading, students read aloud from basal readers for 1 minute. The number of words read correctly constitutes the basic decision-making metric. Maze, a multiple choice cloze reading technique, also has been validated as a CBM testing strategy (Fuchs & Fuchs, 1992). The number of correct word choices per 5 minutes is the primary metric.

2. In spelling, students write words that are dictated at specified intervals (either 5, 7, or 10 seconds) for 2 minutes. The number of correct letters sequences and words spelled correctly are counted.

3. In written expression, students write a story for 3 minutes after being given a story starter (e.g., "Pretend you are playing on the playground and a spaceship lands. A little green person comes out and calls your name and..."). The number of words written, spelled correctly, and/or correct word sequences is counted.

4. In mathematics computation, students write answers to computational problems via 2- to 5-minute probes. The number of correctly written digits is counted.

Upon first inspection, CBM looks like a number of other CBA approaches. For example, when reading is tested, students read connected text aloud in CBM, a process that looks much like an informal reading inventory (IRI). Similarly, students typically read aloud for 1 minute, a process that resembles Precision Teaching (White & Haring, 1981). However, these similarities should not preclude a careful analysis of how CBM is different from other CBA approaches. CBM differs from other CBA approaches on a number of important features. Among its most important features is an emphasis on *standardization*. The technical adequacy of CBM in decision making is demonstrated through specifying carefully the measurement conditions, including directions, scoring, choices of testing material, and interpretation standards. CBM is not an informal (i.e., "anything goes") set of testing activities. As with any standardized test, significant deviation from the standard procedures means that the conclusions drawn from the tests may not be valid.

The more obvious features of CBM, and ones that typically generate considerable discussion among professionals, are that the tests are (a) short (i.e., 1–5 minutes) and (b) emphasize fluency, a combination of accuracy and speed, as the behaviors of interest.

CBM as DIBS

Why would a testing strategy place so much emphasis on a small number of short tests that emphasize fluency? This contrast in testing approaches is very different from most educational testing practices that emphasize long tests with a varied behavior sample that is scored typically in terms of the number correct.

The best way to understand CBM is to characterize CBM as a set of *DIBS*, or dynamic indicators of basic skills. CBM is *dynamic* in that the measures are designed to be sensitive to the short-term effects (i.e., 4–6 weeks) of instructional interventions; they are designed to assess *change*. By using short tests, they can be administered frequently, even weekly, to allow learning to be assessed on a routine basis.

The choice of *fluency* of performance in reading, spelling, written expression, and mathematics computation as the behavior of interest was the result of an ongoing program of research that demonstrated its usefulness in making problem-solving decisions. Beginning in 1978, an extensive program of federally funded research was undertaken to identify key behaviors that would meet the technical requirements to serve as simple, but general, measures of academic performance. Although a considerable body of information has been published on the technical adequacy of CBM in all four academic areas, most research has been conducted on CBM reading measures. See Marston (1989) and Good and Jefferson (1998) for extensive summaries. Results suggest that for most elementary-aged students, counting the number of words a student reads aloud correctly from connected text in 1 minute works extremely well as an indicator of general reading proficiency, including comprehension. Evidence has been garnered with respect to construct validity (Shinn, Good, Knutson, Tilly, & Collins, 1992) as well as traditional conceptions of criterion-related validity, including correlations with other accepted published measures (e.g., Deno, Mirkin, & Chiang, 1982; Fuchs, Fuchs, & Maxwell, 1988) and teacher ratings (Fuchs, Fuchs, & Deno, 1982).

The "I" in DIBS represents that the measures are designed to serve as *indicators* in that they were validated to be correlates of key behaviors indicative of overall performance in an academic area. The CBM measures were *not* designed to represent *all* behaviors that may be included in an academic domain such as reading. For example, Reading-CBM will not provide direct information about whether a student can separate fact from fiction, or identify how compelling is an author's argument. Using CBM also does not mean that they are the *only* tests used to assess students' educational needs. For example, should a teacher be interested in a student's fact versus fiction skills, a measure that assesses this specific skill would be appropriate.

I believe the best metaphor to help understand the use of CBM is to think of the CBM measures as educational thermometers. A thermometer assists the medical community in making a number of general, but key health decisions :

1. Inform whether there is a health problem that warrants further investigation (e.g., a temperature of 101.5° F).

2. Determining the severity of the health problem (101.5° F versus 104° F).

3. Setting goals for a medical intervention (return to 98.6° F with treatment).

4. Evaluating whether the treatment is effective (a reduced temperature to 100.3° after aspirin).

5. When a medical problem is no longer severe (temperature is back within the normal range).

When CBM is used in a Problem-Solving model, its use as an indicator allows for decisions like these made with a thermometer in medicine. Of note also is that like medical thermometers, CBM was not designed to be prescriptive. As with a thermometer that does not inform a physician whether the cause of a high fever is a bacterial or viral infection, or the result of appendicitis, CBM typically does not tell "why" a person has an academic performance discrepancy or how to intervene to reduce it.

The last important distinction to be made about the CBM measures themselves are that in the acronym DIBS, the BS represents the fact that they are designed to quantify student performance in the *basic skills* areas of reading, spelling, mathematics computation, and written expression. They were not designed to draw inferences about a student's skill in content area courses such as science or health education. Although this basic skills focus may appear limited in scope, it is important to note the importance of basic skills in the development of functional literacy (Adams, 1990) and the fact that nearly all students in special education are referred because of severe deficits in these areas.

In sum, CBM's short but repeatable measures from general curriculum were designed to fill a void in educational measurement, especially for students with severe educational needs. They were designed as DIBS to give educators a simple, straightforward way of determining the status of students' "educational health" in critical academic areas, and to provide a mechanism for evaluating the effects of efforts to improve any given student's academic health.

CBM and a Tie to a Problem-Solving Model

CBM can be set apart from other CBA models in that it is tied to an explicit decision-making model (Deno, 1995). It was stated in the first sentence of this chapter that CBM typically is used by teachers to evaluate the effects of their instructional programs. However, usually CBM is used to do more than accomplish this important endeavor. CBM implementation usually occurs in conjunction with implementation of a Problem-Solving model (Deno, 1989, 1995), a heuristic that is composed of five major decisions that are presented in Table 1. Each of the Problem-Solving model decisions is associated with more familiar terms in special education decision-making jargon (e.g., Salvia & Ysseldyke, 1998). Problem-Identification and Problem-Certification decisions, for example, could be considered to be the equivalents of the traditional processes of screening and eligibility determination, respectively. Exploring Solutions could be considered synonymous with instructional planning. With special education students, this process corresponds to the development of an IEP, including setting annual goals and determining intervention plan content and process. Evaluating Solutions relates to pupil progress monitoring while Problem Solution is analogous to program termination or changes in placement to less restrictive settings.

Rather than broad-based, undifferentiated data gathering activities and subsequent decision making, the Problem-Solving model dictates that *specific* information is collected for each step. The need for additional assessment information is decided on a sequential basis. Sometimes assessment activities stop after the first decision (i.e., Problem Identification) should a problem not be validated. Other times, assessment and decision making may occur on a repeated basis throughout a student's educational career spanning years. How CBM is used in the Problem-Solving model will be detailed later in the chapter.

A Problem-Solving model is more than just a set of specified, sequenced decisions (i.e., what is done first, then second, etc.). It is inseparably linked to some foundational assumptions as set forth by Deno (1989, 1995). The Problem-Solving model is predicated on three core assumptions. First, a problem is defined *situationally* as a discrepancy between *what is expected* and *what occurs*. In an academic context, a problem exists when a student does not perform the academic behavior(s) that is expected of him or her in a particular curriculum in a particular classroom, school, school district, or state. The implication of this definition is that "problems" may not be solely the student's "internal problem." What is a problem in one context may not be a problem in another context. Consider the case of two third-grade students, Amy and Billy. Their classroom

663

Table 1. CBM problem-solving model decisions, measurement activities, and evaluation activities

Problem-solving decision	Measurement activities	Evaluation activities	Specific tasks
Problem identification	Observe and record student differences, if any, between actual and expected performance	Decide that a performance discrepancy exists	Peer-referenced assessment
Problem certification	Describe the magnitude of differences between actual and expected performance in the context of likelihood of general education alone solving the problem	Decide if discrepancies are important enough that special services may be required for problem resolution	SLA and identification of alternative intervention options
Exploring solutions	Determine options for annual goals	Decide on annual goal(s) and actual content of intervention to be implemented	Write annual goal based on SLA; identify specific skill or strategy deficits
Evaluating solutions	Monitor intervention implementation and changes in student performance	Determine if intervention is effective or should be modified	Collect progress monitoring data and compare with aimline
Problem solution	Observe and record student differences, if any, between actual and expected performance	Decide if current discrepancies, if any, are not enough and special services may be reduced or eliminated	Repeat peer-referenced assessment and SLA

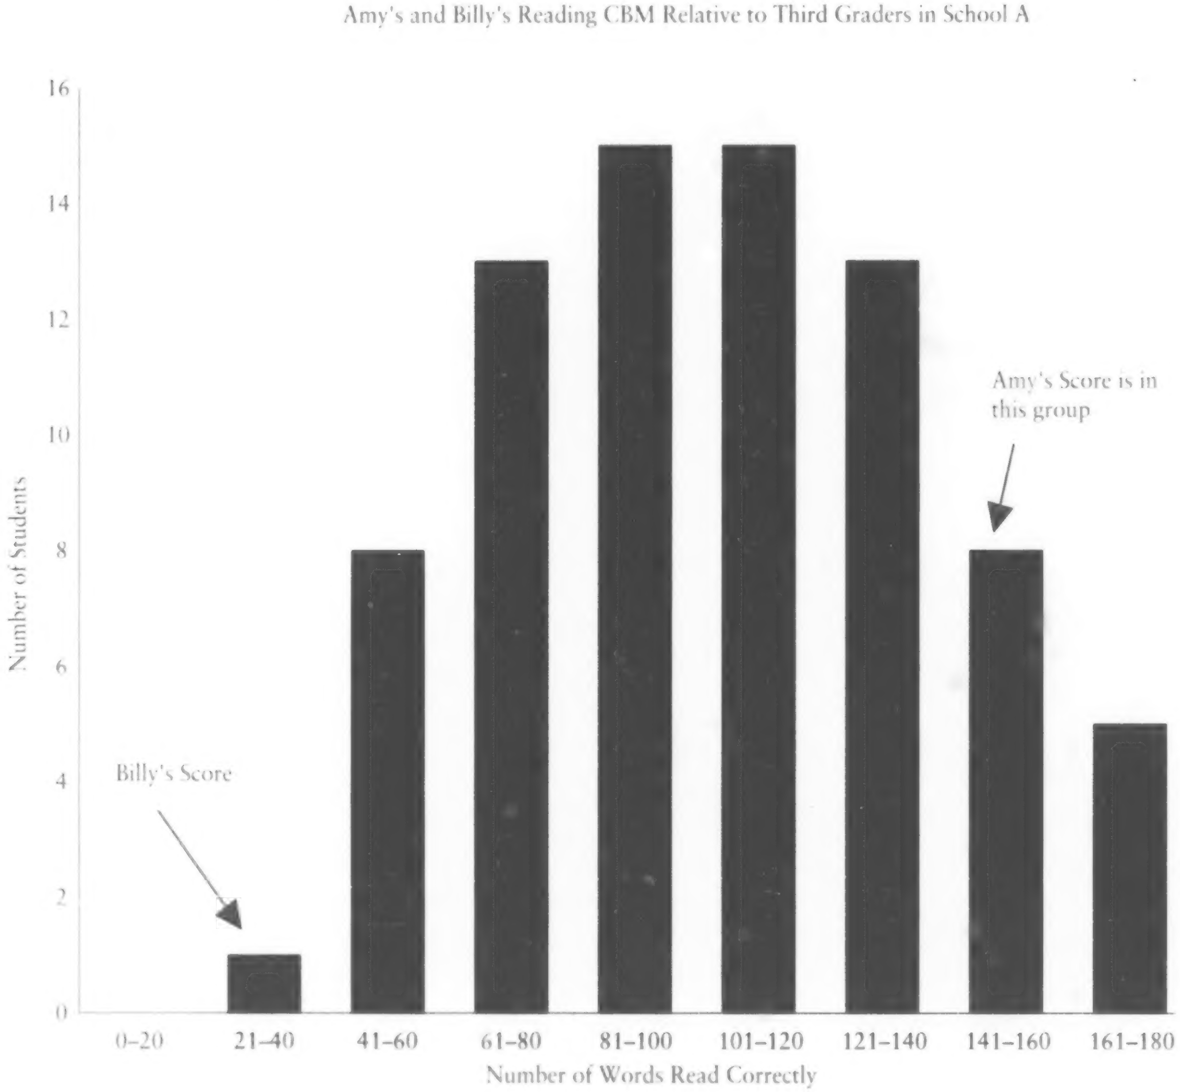
teacher would *expect* them to perform in the third-grade reading curriculum like other students in the classroom. The degree to which they vary from this achievement expectation may result in their reading being viewed as a problem.

With CBM, it is possible to use a data-based decision-making process to describe Amy's and Billy's reading skills and to determine whether there is a problem in a specific environment. Because the CBM measures are dynamic indicators and are of short duration, it is possible to describe the general achievement expectations in particular settings in a time efficient manner by developing local norms. For more information on this process, see Habedank (1995, this volume) or Shinn (1998). In Figure 1, Amy's and Billy's reading skills relative to the achievement expectations in two school systems are compared. The foundation for the frequency distributions displayed in the figure is the result of having all third graders in the two school systems, including Amy and Billy, read three randomly selected passages from the typical level of the third-grade general education reading curriculum. Each student's median score is used for summary purposes. Imagine that Amy's and Billy's median scores on the third-grade reading passages were 141 words read correctly for Amy and 39 words read correctly for Billy.

As displayed in Figure 1, reading skills in the third-grade general curriculum in School A are distributed normally. Relative to these third graders, Amy is in the top quarter of the group in reading skills. Billy, however, is clearly the lowest performing reader. In this situation, although Amy's instructional needs may be similar to a number of other students, Billy may be considered as having a serious reading problem that may require accommodation through problem solving for him to be successful.

In School B, the general curriculum reading skills are not distributed in the same way as School A. The distribution is positively skewed, and a substantial proportion of students are reading very poorly in their third-grade general curriculum. Therefore, problems may be defined differently. Amy, for example, is now the best third-grade reader, and her skills may be so different from others that special accommodations through problem solving may be necessary to meet her instructional needs. Billy is no longer easily identifiable as having a reading skill discrepancy. Out of 52 third-grade pupils, Billy reads as well or better than one-third (17) of the group. It would

Figure 1. A comparison of two students' scores relative to two different environments



be most unlikely that Billy's general education teacher would consider him to have a reading problem that requires some attempts at problem solving in this context. Instead, the data suggest that larger scale *general education problem solving* should be undertaken to meet the educational needs of more students.

In addition to a principle that problems are defined *situationally* as the discrepancy between what is expected and what occurs, the Problem-Solving model assumes that within specific environments, there is a subset of students whose discrepancies are so significant that it may be unreasonable for them to achieve in general education unless their programs are modified (for more detail, see Deno, 1989, 1995, this volume). Currently, it remains a "value judgment" as to when the discrepancy is so severe that special services are warranted, despite repeated attempts to make it quantifiable by using a battery of tests and regression formulas. That is, the exact criterion each state uses for each disability category are specified not by a scientific criterion but by codified judgments. For more detail, see Shinn, Good, and

Parker (1999). By using CBM in a Problem-Solving model with local norms helps decision makers not only operationalize discrepancies, but also to determine whether additional resources such as special education *are needed* to help students benefit from their general education. For example, in School A, Billy has a reading discrepancy that *may* require additional resources. In School B, the educational need (i.e., the performance discrepancy) is not apparent, although it could be argued that significant numbers of third graders in this school need a change in their reading program because so many third-graders are reading so poorly.

The final assumption of the Problem-Solving model is that effective educators must "generate many possible plans of action prior to attempting problem solution" (Deno, 1989, p. 11) and evaluate the effects of the program actually implemented. Presently, we lack the assessment technology to say with certainty what instructional program will work with any student. We cannot say that Billy will benefit from special education (or peer tutoring) in School A *before* we try it out. Therefore, we need to treat all of our interventions as testable hypotheses that must be evaluated formatively for each individual student. Interventions that show strong positive effects when they are evaluated are maintained; ineffective interventions are discarded and/or modified.

BEST PRACTICES

The core CBM test strategies are varied systematically and combined with other pieces of information to make one of five decisions in the Problem-Solving model. Depending on the decision to be made, for example, a student may be tested in different *levels* of a curriculum. For example, when making Problem Identification decisions, a student for whom there is a concern (e.g., a third grader) is tested in the level of the general education curriculum (i.e., third grade) that the typical same-grade peer would be expected to perform satisfactorily in. In contrast, when making Evaluating Solutions decisions, a student is tested on curricular materials that correspond to the level of the curriculum he or she would be expected to perform in 1 year (i.e., the instructional material that represents the annual goal of the IEP).

In addition to systematic differences in the level of the curriculum tested as a function of the decision to be made, the decision-making standards vary as well. One of two approaches is employed: *norm- or peer-referenced* and *individually referenced* decisions. Some decisions in the Problem-Solving model (e.g., Problem Identification) use a norm- or peer-referenced approach. Decisions are made by comparing an individual student's test results to that of a local norm group. This local norm could represent students from the same class, same school, or same school district. For other decisions (e.g., Evaluating Solutions), an *individually referenced approach* is used. The standard is not how a student's performance compares to a group, but how that student's performance compares to his or her previous and expected performances.

Problem Identification

The first step of the Problem-Solving model is Problem Identification. The goal of Problem Identification is to determine in a systematic way if an academic problem exists that is important enough to warrant further assessment (Shinn & Hubbard, 1992). As presented in Table 1, the Problem-Identification process requires a data-based decision about whether a student's performance on academically important tasks (i.e., curriculum tasks) is *significantly discrepant* from that of same-grade peers. For example, in the case of Billy illustrated in Figure 1, at what point is his reading performance relative to other students considered so discrepant that it would be validated as a problem? In School A, his performance is the lowest of third graders, but is it *significantly* different? In School B, his performance was more like those of other students. How much like the other students did he perform? Problem Identification attempts to provide some quantification of the differences in curriculum performance to facilitate decision making.

Problem Identification begins like other school practices when someone, usually a general education teacher or a parent, considers a student's skills to be a concern. This concern usually translates into a referral. However, in contrast to prevailing practices where "referral" is synonymous with *special education* referral and special education eligibility testing, in a Problem-Solving model referrals are made to a *general education* Problem-Solving team (PST). After collecting relevant information on student academic performance using CBM and school and medical history, the PST decides if a problem is validated and is one that may require more extensive problem-solving efforts in the students general education program (e.g., curriculum changes, changes in instructional strategies, Title I) to be resolved. Only if a serious problem were validated that required resources beyond general education alone would more intensive assessment activities such as determining special education eligibility be considered.

This Problem Identification process has a number of advantages over standard practice. The first is one of philosophical approach. From the beginning of the process, not *every* potential problem is viewed as a special education problem. Problem-solving attempts begin with general education interventions. Referrals that are not validated as potentially significant problems may be resolved with general education problem solving and may not require special education at all. Some referral concerns may be remedied based on interventions in general education classrooms identified by the PST. The kind of data collected for Problem Identification is very useful for intervention planning in general education classrooms. The second advantage is that Problem Identification allows for a systematic and timely verification of teacher or parent referral accuracy without the need for special education due process procedures. Although teachers have been demonstrated to be highly accurate in identifying potential student achievement difficulties (Gerber & Semmel, 1984), they also have been shown to be susceptible to gender and ethnicity biases (Shinn, Tindal, & Spira,1987). When there is a significant discrepancy, teacher perceptions of a problem are validated objectively. Parent referrals usually result in expensive assessment practices and lower rates of special education eligibility determination than teachers. By systematically collecting Problem Identification information, the appropriateness of parental concerns can be examined objectively, without expensive special education testing. The third advantage is that the systematic Problem-Identification process can reduce over-testing, an expenditure of limited resources such as school psychologists' and other specialists' time. Those students for whom a problem is not identified are not tested. Terminating testing at this point frees up the persons who normally would collect eligibility information to help general education teachers address the student needs in the classroom.

In operation, Problem Identification relies on a norm- or peer-referenced approach. The referred student's current level of performance in general curriculum is determined by repeated testing over a short period of time in grade-level curriculum materials in the academic area in which the student is considered to be experiencing difficulty. The student's scores then are compared to an expected achievement level and range derived from other general education students. If schools are using CBM in general education promotion and prevention activities, it is very easy to validate problems. *Any* student's CBM scores are compared to those of all the other students and those students with the greatest educational needs (i.e., the largest performance discrepancy) are considered for problem solving.

If schools are not using CBM in general education promotion and prevention activities, then local norms must be developed for Problem Solving. Depending on the degree of school system commitment to a Problem-Solving model, local norms can be derived from students in the same classroom, building, or district. See Habedank Stewart (this volume) for more information on this topic. The discrepancy between the student's actual and expected performance (i.e., the achievement level of typical peers) is calculated and a decision regarding the need for further assessment is made via a cutting score.

A critical feature of Problem Identification is that *repeated* samples of the student of concern's current performance are collected over a period of 3–5 days. Repeated samples provide information about the variability of the student's performance, reduce the effects of "good" days and "bad" days, increase examiner familiarity effects, and allow for a broader sample of academic behavior for intervention planning and reliable decision making.

For illustration of the Problem Identification procedures, consider the case of Sara, who was referred to a PST by her general education teacher during the Fall quarter of third grade because of concerns about her progress in reading and spelling. Because the PST found no obvious reasons for the teacher's concerns (e.g., poor school attendance, vision or hearing difficulties), Sara was tested by a trained member of the PST using a series of third-grade level CBM probes derived from the general education reading curriculum and spelling curriculum. The levels of the reading and spelling curricula were the levels in which the typical third grader was expected to perform. In reading, there were two levels of third-grade readers; typical students were expected to be reading in level 3-2. The PST member had Sara read three different randomly selected passages from level 3-2 for 1 minute, each day for 5 days. The number of words read correctly and errors are recorded, although, for simplification, errors are eliminated in this case study. Sara's reading scores were summarized daily using the median of the three passages.

In spelling, there was only one level of the spelling series. Sara completed a different 2-minute CBM spelling probe with words drawn randomly from all the words in the third-grade spelling book on each of the 5 days. The number of words spelled correctly and in correct letter sequences, a precise measure of spelling skills, is recorded. For illustration, only correct letter sequence scores will be used. Sara's reading and spelling scores are displayed in Table 2. Table 2 also includes third-grade school norms, based on the median reading and spelling scores of 20 randomly selected third-grade students who had been tested using the same materials as part of a school norming process.

To facilitate decision making and increase communication, Sara's scores are displayed in a graph as shown in Figure 2. This figure shows Sara's daily median scores in reading and spelling as well as the median performance of other third-grade students in her school. The peer median is represented by the heavy solid line. To decide if a significant discrepancy exists, Sara's scores must consistently fall below a critical value or cutting score, which is represented in Figure 2 by the double line. In this example, the cutting score was based on a *discrepancy ratio* that is calculated by dividing the peer median score by the referred median student's score. Sara's reading discrepancy score was 3.7. The third-grade peer median of 100 words read correctly was divided by Sara's median score of 27 words read correctly. Her discrepancy ratio was 2.3 (123 correct letter sequences/53 correct letter sequences) in spelling. The most common discrepancy ratio that is used as a cutting score is equal to or greater than 2.0. This score indicates that a student performs at half the fluency (or less) of the typical student in a skill domain. A discrepancy ratio of this magnitude is sufficient to decide that a problem may exist that warrants further assessment.

Discrepancy ratios are used most commonly when local norms are developed for classrooms or schools. When district norms are created, a team has the advantage of percentile ranks, used more conventionally in decision making. Cutting scores based on percentile ranks are determined by finding the raw score that corresponds to an agreed-upon critical level (e.g., 7th or 10th percentile). When a referred student's scores consistently fall below the value of scores at the critical level, a problem is identified. If no obvious explanations exist to account for the discrepancy, then the student may be assessed further in more detail. In the case of Sara, her median scores were converted to percentile ranks and compared to the rankings of her third-grade peers from her school district. In reading, her scores fell below the 2nd percentile; in spelling, her scores were at the 5th percentile compared to the school district's third graders.

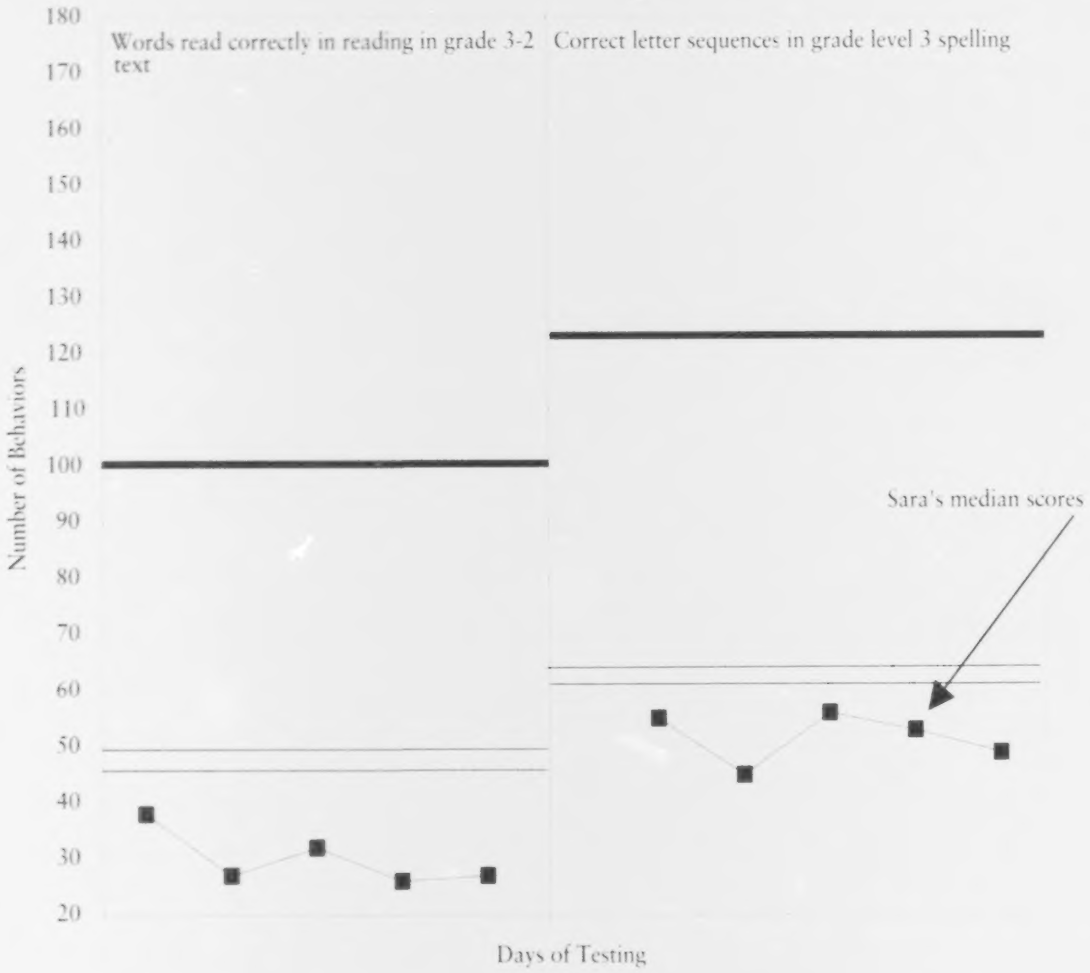
Sara's Problem Identification data consistently were below the discrepancy ratio cutting scores in

Table 2. Results of CBM problem identification testing for Sara

Academic area tested	*Day 1*	*Day 2*	*Day 3*	*Day 4*	*Day 5*	*Overall median*	*Peer median*
Reading grade 3-2 passages							
WRC passage 1	35	16	32	26	29		
WRC passage 2	40	27	42	38	24		
WRC passage 3	38	33	30	24	27		
WRC daily median	38	27	32	26	27	27	100
Spelling grade 3							
Spelling words CLS	55	45	56	53	49	53	123

Note. WRC, words read correctly; CLS, correct letter sequences.

Figure 2. Results of Sara's problem-identification testing in grade 3 reading and spelling probes compared to same-grade peers



reading and spelling. Because the team ruled out educational or medical history as viable explanations for Sara's performance, they decided that further investigation of Sara's reading and spelling skills was warranted. For purposes of illustration, only the results of further assessment in reading will be reported.

Problem Certification

Once a problem is identified, a Problem Certification decision must be made. The major activity is to determine the magnitude or *severity* of the problem. As described in Table 1, Problem Certification is conceptualized as determining whether the difference between actual and expected performance is serious enough that a multi-disciplinary team (MDT) decides that it is unlikely that the academic problem will be resolved with general education resources alone. Once the magnitude of the discrepancy is known and the MDT decides that it is important, the team considers what resources may be available to resolve the problem (e.g., Title 1, peer tutoring, special education). If the MDT decides that the student needs special education to succeed, then eligibility is determined, assuming that procedural state and federal requirements are met (Shinn, Good, & Parker, 1999; Shinn & Hubbard, 1992).

The Problem Certification process begins by conducting a survey-level assessment (SLA) using CBM for each academic area in which a problem has been identified. In SLA, the student is tested in successively lower levels in the curriculum sequence. For example, in Sara's school district's curriculum, there were two levels of third-grade text (3-2, 3-1), two levels of second-grade text (2-2, 2-1), and three levels of first-grade text, exclusive of pre-primers. The data from level 3-2 were obtained already during Problem Identification so there was no need for repeating that testing. Sara was tested using a minimum of three randomly selected passages in each book, beginning with level 3-1 until the level was reached in which she performed successfully. The SLA was completed in one testing session of about 20–30 minutes. The difference between her grade placement and the level of the curriculum in which she could be defined as *successful* would indicate the magnitude of the problem. The results of Sara's SLA are presented in Table 3.

Success can be operationalized in one of two ways: by using normative scores or (b) instructional placement standards. The best way to determine the severity of a problem is to determine the student's *normative score* relative to students with similar acculturation from the same instructional environment (i.e., with local norms). This normative score corresponds to the level of the curriculum in which the tested student's percentile rank score in material from the general curriculum level falls in the average range (i.e., 25th to 75th percentile) of the local norm at that grade. Sara's percentile rank reading scores are included in Table 3. For making Problem Certification decisions, this local norm is based on a sufficient sample size to ensure stable, representative norms. Sara earned reading scores that are clearly outside the average range for students in third and second grade. Sara's score in reading first-grade material was better than most first graders who enter school as non-readers (Shinn, 1988). To facilitate decision making, the SLA information are graphed as shown in Figure 3.

To make Problem Certification decisions, school leaders must establish a percentile rank cutting score below which students can be considered for special education eligibility. See Shinn (1989) or Shinn, Good, and Parker (1999) for more detail on this topic. Sara was declared to be eligible because she performed outside of the average range of students in second-grade who were reading general education second-grade material.

Should local norms not be available, the use of instructional placement standards can contribute to understanding the severity of educational need. Although less precise, these standards can be used to approximate what level of curriculum may be best for purposes of instruction. For example, one standard that has been explored for reading when first- or second-grade levels of the curriculum are considered *and* students are to receive teacher-led instruction is that students are placed in the highest level in which they read between 40 and 60 words correctly per minute. Students also must have high accuracy, about 90–95% or 4–6 errors per minute. For third- through sixth-grade reading curriculum, students are placed in the highest level in which they read between 70 and 100 words correctly per minute. A higher fluency standard is required because of the increased cognitive complexity of the reading materials. Again, it is assumed that the majority of their reading instructional program is teacher directed.

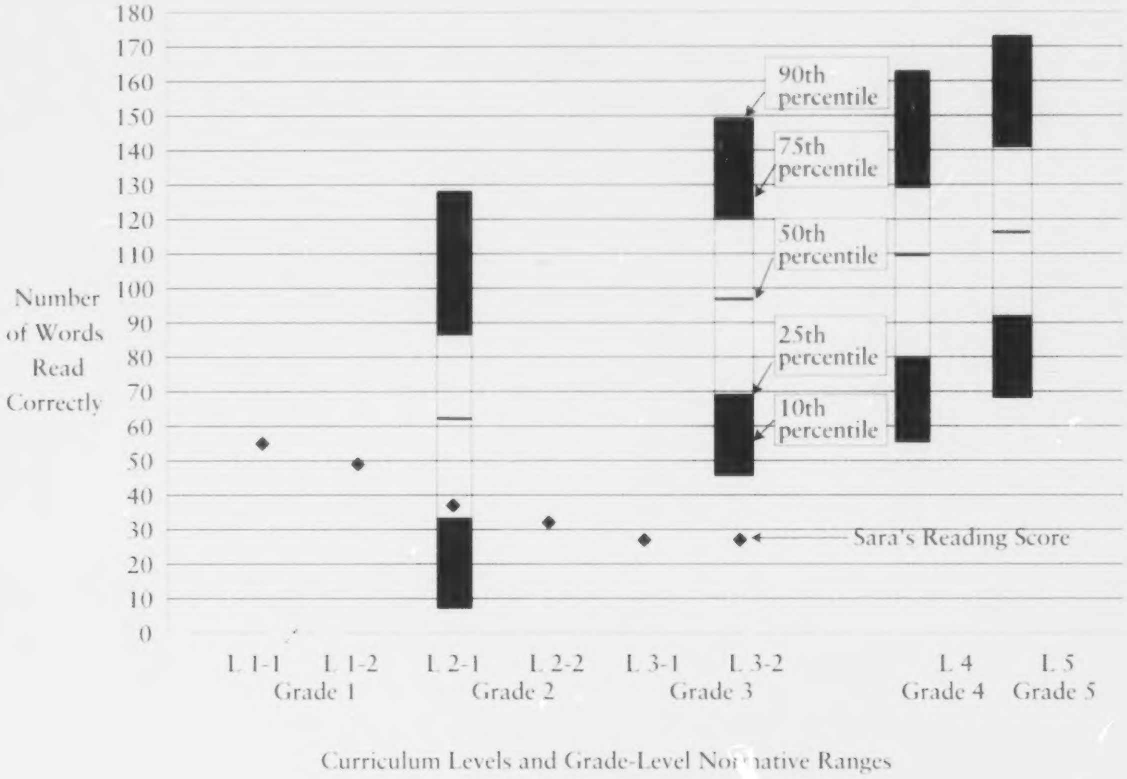
These reading instructional placement standards are represented in Figure 4 to facilitate communica-

Table 3. Reading SLA for Sara with curriculum level and performance relative to local norms

Level of Ginn curriculum	*Sara's median performance*	*Grade-level peer performance*	*Sara's percentile rank*
3-2	27	100	2nd
3-1	27	NA	NA
2-2	32	NA	NA
2-1	37		15th
1-3	49	NA	NA
1-2	55	—[a]	—[a]

[a] No first-grade students were tested in the Fall because most students entered with limited reading skills.

Figure 3. Results of Sara's SLA assessment in reading, comparing her performance to same- and other-grade general education students



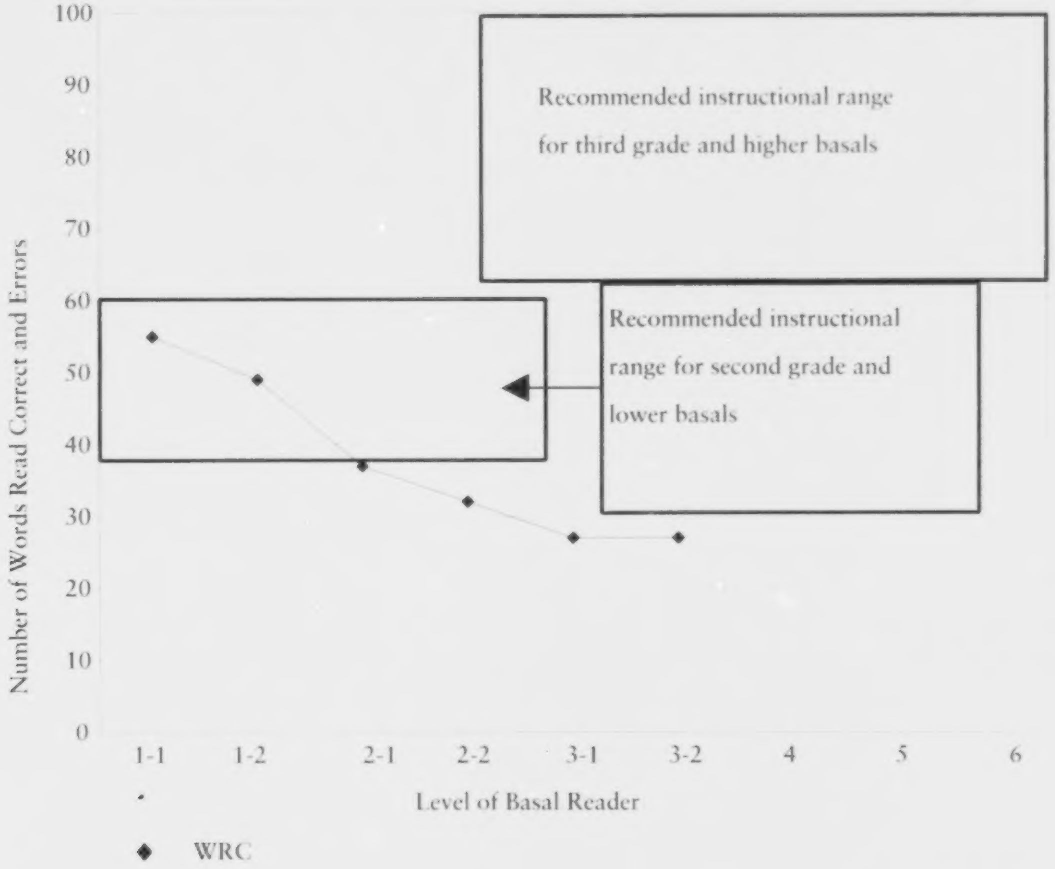
tion. The placement standards are marked by the dark bands. Sara's scores relative to the bands also are displayed. Clearly, her reading performance in third- and second-grade levels of the curriculum is too low for her to be considered successful in that material. The highest level of the curriculum in which she meets the instructional standards is the level 1-3 book (see Table 5). By comparing her expected grade placement, if she were considered a typical student, to her recommended instructional placement, it could be concluded that she is approximately 2 years behind according to the publisher's scope-and-sequence chart.

The second part of the Problem Certification decision involves considering whether the student needs special education to benefit from their education. A student may not need special education services, even though they may meet the eligibility criterion (Rothstein, 1990; Shinn & Hubbard, 1992). Need is determined by examining the student's instructional needs in the context of resources available in general education that may resolve the problem. Only after considering Sara's reading performance in the context of the adequacy of her general education instructional environment, her behavior in that environment, other instructional opportunities available (e.g., lower reading group, peer tutoring), and previous achievement, health, social, and family factors, did the MDT determine that it was unlikely that the problem would be resolved with general education resources alone.

Exploring Solutions

If schools are well-practiced in any assessment activity, it is in testing for purposes of determining special education eligibility. Thus far, this chapter has described the use of CBM within a Problem-Solving model to provide a *needs-based* alternative assess-

Figure 4. Reading survey-level results for Sara



ment approach that arguably works as well or better than conventional eligibility determination activities (Shinn, 1989; Shinn, Good, & Parker, 1999). In part, the advantage of using CBM in Problem Solving for these purposes is the fact that performance and educational need in general curriculum are measured and decisions are tied to specific school performance expectations allowing for conclusions about the least restrictive environment (LRE) to be drawn.

Unfortunately, schools are less well practiced and proficient in assessing students for the purposes of special education intervention planning and evaluation. Using CBM within a Problem-Solving model can remedy this situation. The Problem-Solving model makes explicit the importance of assessing performance in general curriculum for intervention planning during the Exploring Solutions decision. Using CBM in a Problem-Solving model allows a linkage between assessment for eligibility purposes and intervention planning. As will be seen later in this chapter, the use of CBM also allows linkages between assessment for eligibility purposes and intervention planning to intervention evaluation.

As presented in Table 1, the purpose of Exploring Solutions is three-fold: to specify (a) the data-based goals of the intervention in general curriculum, (b) the *content* of the intervention or "what to teach," and (c) the *how* to deliver the intervention or "how to teach." CBM is extremely useful for the goal setting component of Exploring Solutions. Although not useless for intervention planning, other CBA models are more suitable for determining intervention components and processes. Howell's curriculum-based evaluation (e.g., Howell & Nolet, 1999) is especially well-suited for making intervention planning decisions.

677

GENERAL GOAL SETTING APPROACH

CBM's linkage between eligibility assessment and intervention planning begins by using the data collected during Problem Identification and Problem Certification to *develop intervention goals* in general curriculum for the student (Fuchs & Shinn, 1989; Shinn & Shinn, 2000). The mechanism for goal setting is the annual goal of a student's IEP. The basic *idea* is simple and works much like conventional practice: annual goals are based on identifying "where the student is now" and where in general curriculum the IEP team would like the student to perform in 1 year if special education services are effective. What differs from conventional practice is that when using CBM it can be determined more directly "where the student is" in general curriculum. This decision is not made using grade-equivalent scores from tests that may not measure a student's curricular skills. Instead, the decision is made by testing students *directly* in the general curriculum they would be expected to learn in general education classrooms. Similarly, expectations about future performance are not gross extrapolations from a test's grade equivalent scores, but are based on SLA in curriculum level materials a student would be expected to perform in 1 year.

This process can be illustrated using the case study. Sara's SLA data showed her as "successful" in the grade 1, level 3 general education reading book. In 1 year, according to the publisher's scope-and-sequence, typical students would be expected to perform proficiently in level 2 of the grade 2 basal. The IEP team individualizes the annual goal by discussing the expectations for individual students. If the IEP team wanted to write a goal that facilitated Sara's catching up (i.e., reducing the discrepancy), they may want her to perform proficiently in a third-grade or even fourth-grade level of the basal series in 1 year. In Sara's case, the IEP team decided that they would consider the special education program to be successful if she performed proficiently in the level 3-2 general education basal reader in 1 year.

WRITING THE ANNUAL GOAL

Annual IEP goals based on CBM data are written in the format of traditional behavioral objectives, and consist of a *behavior* to be measured, *conditions* for attainment, and *criterion* for success. The basic format in reading, math, written expression, and spelling is illustrated in Table 4.

CBM IEP goals use a long-term goal approach to goal setting. In a long-term goal approach, measure-

Table 4. Basic format for CBM annual IEP goals in reading, math, written expression, and spelling

Academic area	*Conditions*	*Behavior*	*Criterion*
Reading	In *(number of weeks until annual review)*, when given a randomly selected passage from *(level and name of reading series)*	Student will read aloud	At *(number of words per minute correct/number of errors)*
Math	In *(number of weeks until annual review)*, when given a randomly selected problems from *(level and name of math series)*, for 2 minutes	Student will write	*(Number of correct digits)*
Written expression	In *(number of weeks until annual review)*, when given a story starter or topic sentence and 3 minutes in which to write	Student will write	A total of *(number of words or letter sequences)*
Spelling	In *(number of weeks until annual review)*, when dictated randomly selected words from *(level and name of spelling series)*, for 2 minutes	Student will write	*(Number of correct letter sequences)*

Note. From L. S. Fuchs and M. R. Shinn, "Writing CBM IEP Objectives" (p. 136). In M. R. Shinn (Ed.) *Curriculum-Based Measurement: Assessing Special Services Children.* New York: Guilford Press. Copyright 1989 by The Guilford Press. Reprinted by permission.

ment of progress toward the goal is designed to answer the question, *Is the student becoming more proficient in reading, math, writing, or spelling in the general education curriculum?* This approach has an advantage over most common long-term goals (e.g., "Will improve 1 year in spelling.") in that they are observable, measurable, and are tied directly to a validated way of *formative evaluation.* With formative evaluation, effective interventions that are identified during instruction are maintained; ineffective interventions are modified.

This long-term goal approach also avoids the numerous difficulties with short-term measurement (e.g., "Will master multiplication facts with 80% accuracy") that are problematic because they are tied to specific units or small skills within a curriculum. The advantages of using CBM and a long-term goal approach are discussed in more detail in Fuchs (this volume) and in Fuchs (1993) and Fuchs and Deno (1991).

The goal-setting process begins with identifying the academic area in which the goal is to be written. Once the academic area is specified, the dynamic indicator for that content becomes the behavior to measure. Therefore, because Sara requires an annual goal in reading, the IEP team knows that the behavior component of the goal is oral reading.

The second step is establishing the goal's *conditions.* The *time frame* is the time at which the goal is expected to be accomplished. In Sara's school system, all IEP goals expired on their anniversary date, 1 year from the time of writing. Therefore, Sara's annual goal would begin, "*In 36 weeks (1 academic year)...*" The next task is *specification of the level of curriculum* the student will be expected to perform proficiently in in one year. This task requires knowledge of the general education curriculum scope-and-sequence, a judgment of how much is expected to be accomplished, and the ramifications on how the problem is defined. For example, writing an annual goal so that a special education student is expected to make less than 1 year's growth in general education curriculum is constructing an intervention that will leave a student further behind general education peers *and* the intervention would still be considered effective! Writing an annual goal so that a special education student is expected to make more than 1 year's growth in general education curriculum is constructing an intervention that, if successful, will make the student's skills more like general education peers. See Fuchs and Shinn (1989) and Shinn, Deno, and Fuchs (in press) for more detail. Because Sara's IEP team specified level 3-2 as the annual goal material, when combined with the time frame and the behavior, her goal so far would read as follows: "*When given a randomly selected passage from level 3-2 of the ABC curriculum, Sara will read aloud...*"

The final task in setting annual goals requires specification of a *criterion for performance.* The question for Sara is, *How well do we want her to read the level 3-2 basal if her intervention program is to be considered successful?* Two broad approaches can be used to identify a criterion for success, with or without local norms. When local norms are available, the IEP team can use the level of performance of typical students in the level of the curriculum identified in the conditions section as the criterion. For example, in Sara's case, because the IEP team distinguished book 3-2 as the level of the curriculum they desired in 1 year, they could expect that Sara will read it as well as the typical third-grader in the Fall or 100 words read correctly. Alternatively, they could expect that Sara would read the level 3-2 reader as well as an end-of-year third grader or 133 words read correctly.

In the absence of local norms, other strategies may be used to identify a criterion for success on the annual goal. *Expert judgment* requires that IEP teams use as an organizer that the student be expected to perform at a significantly higher level in a more difficult level of the curriculum in 1 year. The use of *instructional placement standards* is another strategy for goal setting without local norms. It is based on the setting the criterion for success at a level of performance such that the curriculum is appropriate for instructional purposes for the student in 1 year. In reading, for example, the IEP team could use the instructional placement standards given earlier in the chapter. Using this approach in Sara's case, the criterion for success could be that in 1 year she would read a randomly selected passage from level 3-2 between 70 and 100 words correctly. It is important that a more specific value is used rather than a range. If a high level of proficiency is expected, then the IEP team could select the upper end of the range (100 words read correctly) as the criterion for success. If a lower level of proficiency is satisfactory, then the IEP team could select the lower end of the range (e.g., 75 words read correctly). See Fuchs (this volume) and

Fuchs and Shinn (1989) and Shinn, Deno, and Fuchs (in press) for more information on writing annual goals using CBM.

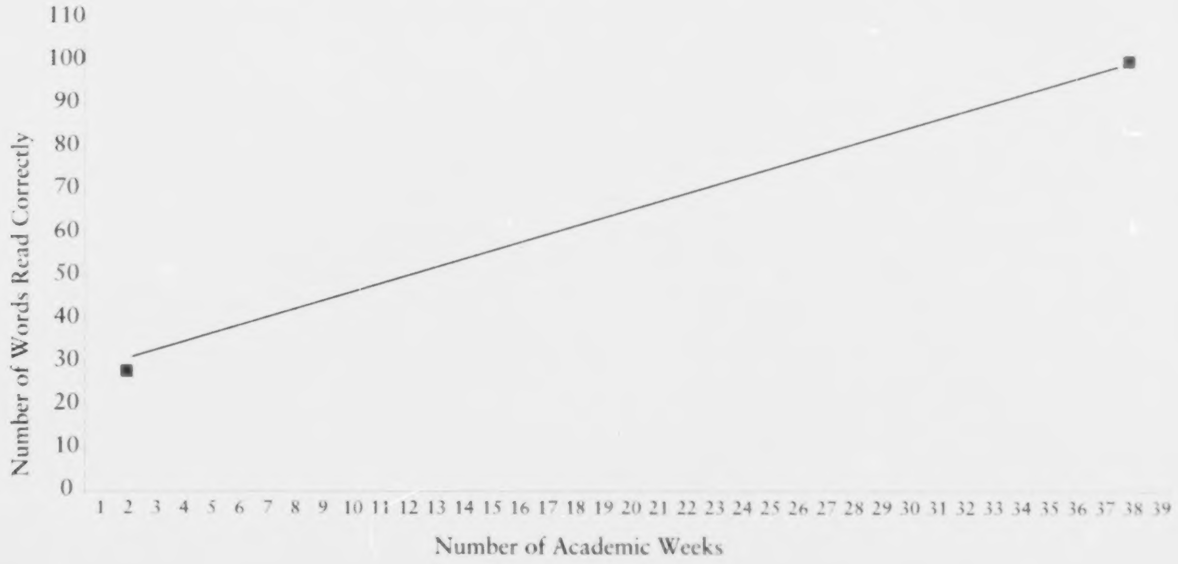
The actual IEP annual goal written by Sara's IEP team was as follows: *When given a randomly selected passage from level 3-2 of the ABC curriculum, Sara will read aloud 100 words correctly per minute.* The team also added an accuracy criterion that she would read a randomly selected passage with five or fewer errors (approximately 95% accuracy). This goal was based on a rationale to have Sara proficient in an end-of-third-grade reader by the time she was in fourth grade. The team considered reading at 100 words correctly, the median level of third graders in that level in the Fall, as proficient.

Evaluating Solutions

The use of CBM SLA data to write annual IEP goals links assessment for eligibility decision making to intervention planning. The use of CBM IEP goals links intervention planning to intervention evaluation by providing a standard for determining intervention effectiveness. As presented in Table 1, the purpose of Evaluating Solutions is to monitor student progress toward IEP goals and determine an intervention's effectiveness. As with other decisions in the Problem-Solving model shown earlier, the annual goal can be represented graphically as shown in Figure 5 to clarify communication of expectations. In the figure, her initial survey-level data in level 3-2, the annual goal material, represents her current performance. The intersection of the criterion for success (100 words read correctly) and the goal date (36 weeks) forms her *aim*. The line drawn from her current performance to her aim forms her aimline or *expected rate of progress*. By comparing her actual rate of progress, the *trendline*, determined by collected samples of her reading from level 3-1 over time, with her expected rate of progress, a decision can be made about treatment effectiveness and the need for program modification. When the actual rate of progress exceeds the expected rate of progress, the student's goal is raised. When the actual rate of progress is below the expected rate of progress, the student's intervention program is changed. See Fuchs (this volume) and the work of Lynn and Douglas Fuchs for more information on this topic.

Progress monitoring data usually are collected once or twice per week by a special education teacher delivering the intervention or via a microcomputer (Fuchs, 1998; Fuchs, Hamlett, & Fuchs, 1999). In reading, students read one probe each testing occa-

Figure 5. Graphic display of Sara's IEP goal translated into expected rate of student progress



sion. Testing items are selected from a pool that represents the domain of *all* the items from the goal level of the curriculum. With Sara, this would represent a sample from all passages in the level 3-2 basal reader. Probes are created by randomly selecting subsets of items from this large pool and student progress is measured repeatedly on these probes. This process produces a set of parallel form CBM probes with known technical adequacy.

The results of testing Sara one to two times per week using randomly selected reading probes from level 3-1 are shown in Figure 6. The data are plotted soon after testing on an equal interval graph. A minimum of 10 data points is suggested before a reliable decision can be made about the effectiveness of an intervention program (Good & Shinn, 1990).

On Sara's graph, after the first 10 data points, it is clear that she is meeting or exceeding her expected rate of progress; nine of the 10 data points are above the aimline. This is a good indication that the instructional intervention is effective and should be maintained.

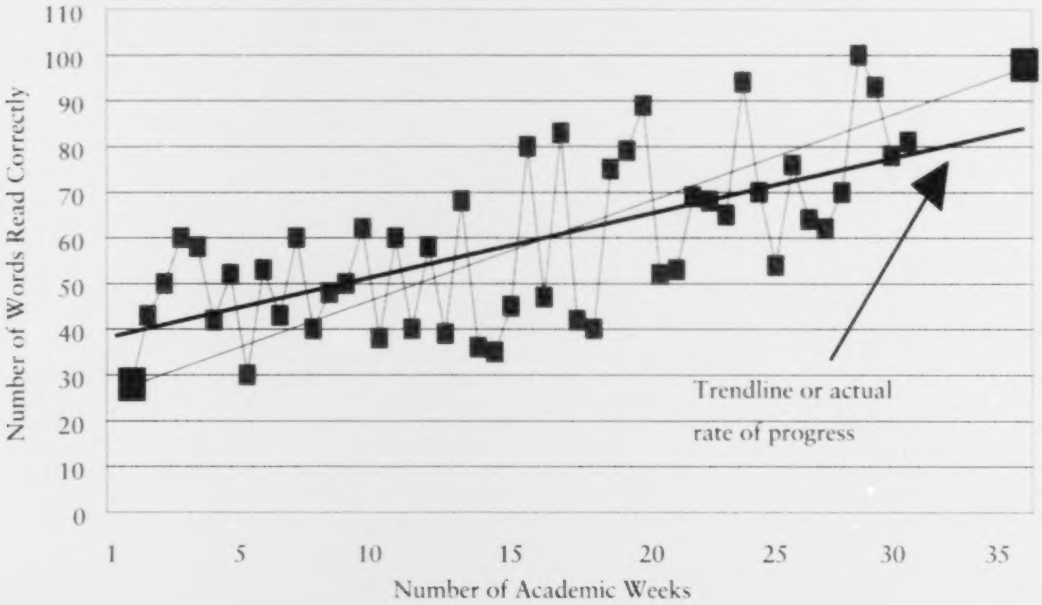
As the school year goes on, Sara's teacher continued to evaluate her progress routinely. At the end of the academic year, she had been tested 47 times during the 30-week period. Her overall rate of progress, the trendline, is represented by the heavy black line that is calculated by drawing an ordinary least squares regression line through all the data. The trendline corresponds closely to the slope of the aimline, indicating an intervention program that is effective.

As mentioned earlier in the chapter, when the effects of instructional interventions are examined systematically and continuously, educators can make data-based decisions about whether to maintain or change interventions. Students need not receive instructional programs that do not meet their needs for long periods. Unsuccessful interventions can be changed to better meet students' needs. Educators need not discard or modify programs that may be working. The net result is that student achievement outcomes are improved significantly (Fuchs, Deno, & Mirkin, 1984; Fuchs & Fuchs, 1986, 1999).

Problem Solution

It can be argued persuasively that the kinds of testing activities that characterize long-term decisions about students' educational needs (e.g., annual reviews or special education exit) are little more than psychome-

Figure 6. Graphic display of Sara's rate of progress relative to her IEP goal



tric superstitious behavior. Annual reviews rely heavily on published achievements tests that were not designed to evaluate the progress of individual students (Carver, 1974; Marston, 1989). Special education exit decisions occur so rarely that part of the problem must be related to measurement of outcomes. It is estimated that no more than 2% of special education students are exited each year (Fuchs, Fuchs, & Fernstrom, 1993). However, considerable numbers of these students have academic skills equal to those of general education students. For example, it has been demonstrated that in at least three school districts, 30–40% of special education students served more than 2 years in a pull-out program with an IEP objective in reading read as well or better than other low-performing readers in their general education classroom (Shinn, Baker, Habedank, & Good, 1993; Shinn, Habedank, Rodden-Nord, & Knutson, 1993). These students had not been considered for termination.

A Problem-Solving model resolves some problems in determining students' long-term needs and the appropriateness of continued special education services. As presented in Table 1, Problem Solution decisions are tied conceptually to the assessment activities that defined the problem in the first place. Is there *still* a discrepancy between what is expected for the student and how the student performs? Procedurally, the discrepancy is measured again and is augmented by study of the special education student's rate of progress toward his or her IEP annual goal.

The logical time to make Problem Solution decisions is during the periodic and annual reviews that are required by law (Rothstein, 1990). To date, periodic reviews rely heavily on informal subjective opinions of the teacher with responsibility for the intervention plan. Rarely are data collected or analyzed systematically specifically for this purpose. Annual review decisions usually are more structured and are oriented around the collection of student outcome information. CBM data can be collected efficiently at both periodic and annual reviews.

PERIODIC REVIEWS

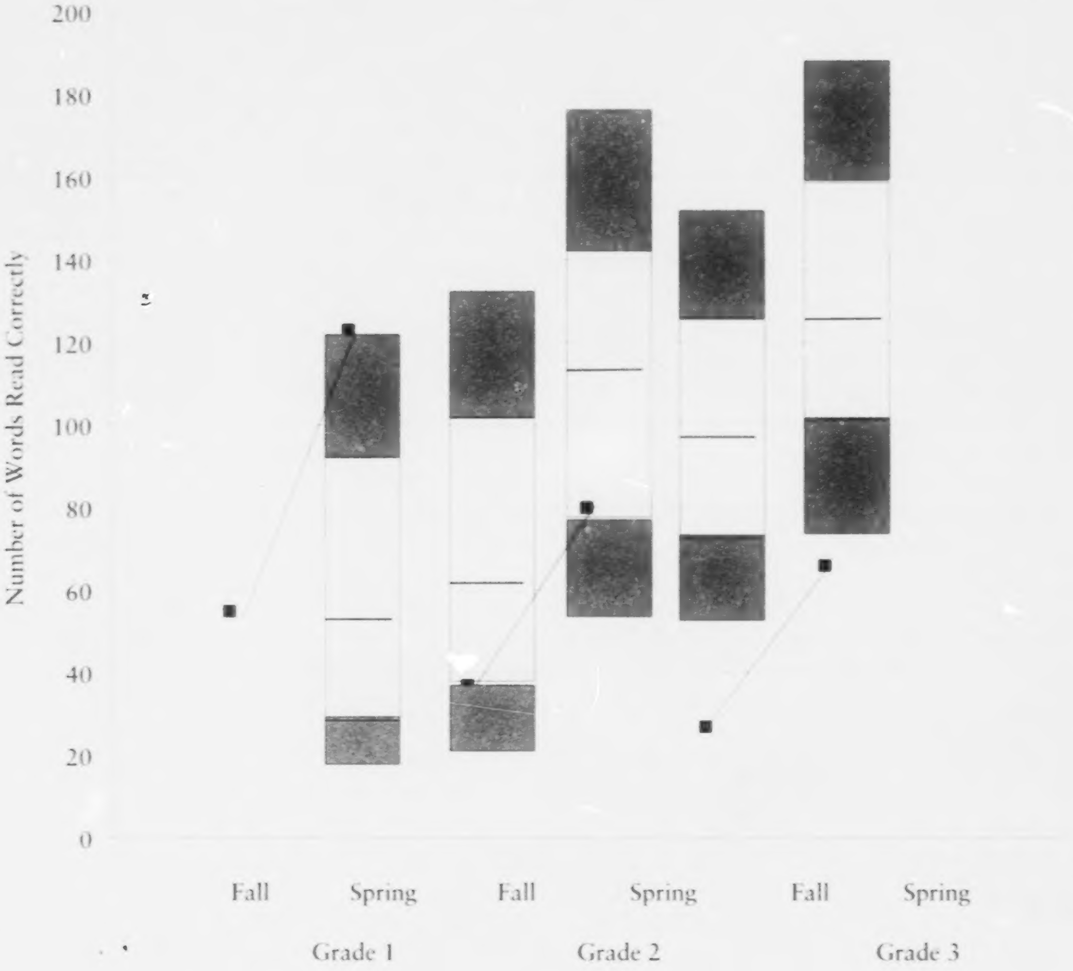
Periodic reviews are conducted with two pieces of CBM assessment data: the student progress graph and new peer-referenced testing results. These data are used to answer the questions, *Is the student making progress?* And if so, is the progress "important?" The first question is answered by examining the student's graph showing the rate of progress toward the IEP annual goal. As in making Evaluating Solutions decisions, intervention effectiveness is determined by comparing the student's trendline to the aimline. If the trendline exceeds the aimline, then two explanations are possible: Either the intervention is effective or the annual goal is too low. If the trendline is below the aimline, then two other explanations are possible: Either the intervention program may be ineffective and needs to be changed or the student's annual goal may be too high.

The second question about the importance of the student progress helps separate out issues of intervention effectiveness and goal appropriateness. Student change is defined as "important" if it results in *reduced discrepancies*. Data to make this decision are collected by testing the special education student in a norm-referenced manner like in Problem Identification. Again, random samples of the curriculum from the student's expected grade placement are used for testing. However, unlike Problem Identification, this testing takes place in one sitting rather than by collecting repeated samples over time. The student's scores are compared to same-grade peers, using the type of summary metric that was employed in Problem Identification.

Changes in discrepancy ratios or percentile ranks are noted. Reduced discrepancies indicate that the special education student has made meaningful, important growth. When combined with the student IEP graph information, the change in relative standing allows for an evaluation of a student's overall special education program, including intervention effectiveness and goal appropriateness. The use of these types of data is illustrated in the case study. A periodic review was conducted with Sara the first trimester after her special education certification (Winter), approximately 10 weeks after her special education placement. Her IEP progress graph at week 10 showed her consistently scoring at or above her aimline (see Figure 7). Sara also was tested using three randomly selected passages from the same level of the reading series as her initial Problem Identification testing. This process took less than 10 minutes. Her scores, summarized in percentile ranks, are shown in Table 5. The number of words she read correctly increased to 52 and the magnitude of the discrepancy decreased from performance at the 2nd percentile compared to same-grade peers to the 4th percentile.

632

Figure 7. Fall and Spring SLA results for annual reviews



Both pieces of data indicate that the progress she is making toward her IEP goal is educationally meaningful; that is, she is reducing the reading skill discrepancy. If she were achieving her IEP goal, but not reducing the discrepancy, then we could conclude that perhaps the IEP goal was not ambitious enough to result in real improvement. Conversely, if she were not making progress toward her IEP goal, but was reducing the peer discrepancy, then it could be concluded that her goal was too ambitious and should be lowered.

Annual Reviews

The annual review process is a more in-depth assessment of a student's skill level and rates of progress. Again, progress toward the IEP annual goal is investigated by comparing actual versus expected student progress on the student performance graph. As can be seen in Sara's graph, at week 30 when the annual review was conducted her actual rate of progress paralleled her expected rate. Overall, the annual review team believed the special education intervention to be effective and considered her to have attained the annual goal. Some concern was expressed over the current effectiveness of the program, however, as seven of the last 10 data points fell below the aimline.

For annual reviews, more information is collected on the current severity of the problem with a new SLA identical to the one conducted during Problem Certi-

Table 5. Periodic and annual review reading assessment as part of problem solution decisions for Sara in reading

Level of curriculum	*Sara's Fall median WRC*[a]	*Sara's Fall percentile*[a]	*Sara's Winter median WRC*[b]	*Sara's Winter percentile*	*Sara's Spring median WRC*[a]	*Sara's Spring percentile*[a]
3-2	27	2nd	53	4th	69	6th
3-1	27	NA			66	NA
2-2	32	NA			81	NA
2-1	37	15th			80	26th
1-3	49	NA			106	NA
1-2	55	NA			123	89th

Notes: WRC, words read correctly.

[a] Based on SLA.

[b] Peer-referenced testing compared to same grade-students only.

fication. Not only are the SLA data used to determine problem severity, but they are also used to write the annual goal for the next year. The results of Sara's annual review SLA are also presented in Table 5. Sara's number of words read correctly improved again in third-grade material and the discrepancy from peers was reduced as she improved from the 4th to the 6th percentile. Her reading skills also improved significantly from Fall in all levels of the general education reading series.

Annual review SLA results can be displayed graphically to show the growth relative to norm groups as shown in Figure 7. With adequate progress toward the IEP goal and a reduced discrepancy, the team considered the intervention successful and discussed Sara's continued *need* for the intervention.

A key decision in Problem Solution is determining when additional resources such as special education are no longer needed. In a Problem-Solving model, this decision is reached when the discrepancy is no longer important; that is, special education students' skills are within the range of students in general education classrooms. In this instance, students may be exited from special education and returned for instruction in less restrictive environments. For more detail on this topic, see Shinn, Powell-Smith, Good, and Baker (1997), Shinn, Powell-Smith, and Good (1996), and Powell-Smith and Habedank (1998). Use of CBM to assist in making special education exit decisions resulted in an increase from 4% of special education students exited on an annual basis to 20% (Marston & Magnusson, 1988).

SUMMARY

CBM is a consistent and continuous measurement system that was designed to function as DIBS. These DIBS are to be used as educational thermometers, tools to identify an academic problem and to decide whether the intervention for that problem is effective. CBM is inextricably tied to a Problem-Solving model in which data are used to guide decision making. Decisions are tied to general education curricula and often to how typical students perform in that curriculum. However, the critical feature that defines CBM is the collection of data on repeated standard tasks for *individual* students. When used to evaluate and modify instructional intervention programs for individual students, research findings consistently have found significantly improved outcomes. Programs for special education students are improved by allowing for validation and modification of individual interventions, better IEPs can be written, and assessment can be linked to intervention. Because most CBM data are collected by trained special education and general education teachers, with consultation and supervision by school psychologists, the special education eligibility testing load for school psychologists can be reduced substantially. This reduction in testing load can be used to increase the amount of time school psychologists spend in indirect and direct service provision to all students in America's schools.

One of my mentors once paraphrased an old saying, commenting, "school psychologists are trained to admire (i.e., identify) problems, not solve them."

In more ways than one, CBM and its use in a Problem-Solving model allows for this conception of school psychology practice to change.

ANNOTATED BIBLIOGRAPHY

Deno, S. L. (1991). Individual differences and individual difference: The essential difference of special education. *The Journal of Special Education, 24*(2), 160–173.
In this article, the current aptitude-treatment interaction instructional technology is examined and determined to be insufficiently responsive to individual differences of students. Instead, a formative evaluation model is proposed as an idiographic approach to building more effective programs for individual students. In this model, aptitude differences at the outset of a program are deemphasized and methodology for tailoring programs to individual students during instruction becomes the focus.

Fuchs, L. S. (1994). *Connecting performance assessment to instruction.* Reston, VA: Council for Exceptional Children.
This monograph lays out the basic details of the necessary features of any assessment system that is designed to improve student achievement outcomes. It should be standard reading for anyone interested in assessing student achievement for instructional planning and educational outcomes.

Fuchs, L. S., & Deno, S. L. (1991). Paradigmatic distinctions between instructionally relevant measurement models. *Exceptional Children, 58*, 232–243.
This paper serves as a primer for comparing the advantages and disadvantages of types of outcome monitoring assessment systems, including specific sub-skill mastery measurement (short-term goal approach) and general outcome measurement (long-term goal approach) progress monitoring. General outcome measurement emerges as the most advantageous method for monitoring student progress. A case study is presented to illustrate the differences between approaches.

Fuchs, L. S., & Fuchs, D. (1999). Monitoring student progress toward the development of reading competence: A review of three forms of classroom-based assessment. *School Psychology Review, 28*(4), 659–671.
This paper serves as an updated critique of methods of monitoring student achievement outcomes according to a set of standards that includes technical adequacy and feasibility.

Shinn, M. R. (Ed.) (1989). *Curriculum-Based Measurement: Assessing special children*. New York: Guilford.

This book contains contributions of the work of the core-group of researchers and school practitioners (Deno, L. Fuchs, Marston, Shinn, Tindal, Allen) who developed and implemented CBM. Specific procedures for implementing CBM in school settings are detailed. General background information and conceptual issues surrounding the development and use of CBM as an alternative to traditional school psychology practice are discussed also.

Shinn, M. R. (Ed.). (1998). *Advanced applications of Curriculum-Based Measurement*. New York: Guilford.

This edited book presents information on a range of applications of CBM to Problem Solving, including points of confusion, use with English-Language Learners and computers.

AUTHOR NOTE

This chapter was supported in part by grant No. 84.029D60057 Leadership Training in Curriculum-Based Measurement and Its Use in a Problem-Solving Model sponsored by the U.S. Department of Education, Office of Special Education Research. OVERVIEW

Reading is an educational outcome essential to academic achievement and, ultimately, success in life. Children who develop good reading skills are more likely to succeed at school and become productive members of our society (Adams, 1990). However, children who develop poor reading skills are more likely to experience academic and behavioral difficulties at school (Schenk, Fitzsimmons, Bullard, Taylor, & Satz, 1980) and be at risk for later problems such as juvenile delinquency, truancy, and substance abuse (McGill-Franzen, 1987). Children considered at especially high risk for this scenario include those from economically disadvantaged homes as well as those with special needs (Marvin & Mirenda, 1993; National Research Council, 1998; Rush, 1999). For example, in 1998, nearly 4 in 10 fourth-grade children nationwide failed to achieve even partial mastery of the reading skills needed for school success. In schools with the highest levels of poverty, nearly 70% of fourth-grade children failed to read at this basic level (Donahue, Voelkl, Campbell, & Mazzeo, 1999). These data are alarming. How educators respond to the data will determine whether or not these trends in reading achievement can be reversed.

Few people would dispute that helping children become proficient readers must be a priority for elementary schools. The recent focus at the national level on reading (e.g., Goals 2000: National Reading Summit, 1998; Reading Excellence Act, 1999) has prompted state departments of education and school districts to establish standards for reading achievement by the end of third or fourth grade. In Iowa, for example, the Department of Education requires that reading achievement be evaluated and reported by districts to the public in the fourth grade. Figure 1 shows aggregated student reading achievement data from the Iowa Test of Basic Skills (ITBS) that will be reported to the public by all districts. Districts will report percentages of students in three performance categories, Low, Intermediate, and High. Students are categorized based on their performance relative to national ITBS norms from 1992. Two problems are apparent in this figure. First, over one in four fourth-grade students were judged to be low proficiency readers. Second, the percent of students judged to be low proficiency readers is increasing while the percentage of students in the high groups is decreasing. A primary limitation of the data gathered is that they are summative. By third or fourth grade, students are performing well below their peers, and it is too late to modify beginning reading instruction to promote the acquisition of initial reading skills. What is needed for prevention of reading failure is to *begin early* and *assess dynamically.* The purpose of this chapter is to describe the use of Dynamic Indicators of Basic Early Literacy Skills (DIBELS) in an Out-

Figure 1. Fourth grade reading achievement levels on Iowa Test of Basic Skills

comes-Driven Model to identify children early who may need additional instructional support, and to evaluate and modify instruction on an ongoing, formative basis to ensure that all children achieve high stakes reading goals.

Begin Early

The path to reading proficiency begins long before children begin school and receive formal reading instruction. Literacy development begins in infancy as children learn to communicate using oral language and grows as children are exposed to print and gain awareness of the connection between print and oral language. To prevent reading difficulties and promote reading success, it is essential that preschool children receive early and appropriate learning experiences that promote the acquisition of early literacy skills. The quality of these experiences will contribute to later school success and the prevention of future school problems, thus lessening the risk of secondary disorders (e.g., behavioral problems, substance abuse).

It is apparent from the research base, however, that simply preparing children for kindergarten is not enough. Much of the early efficacy research on Head Start, for example, has focused on longitudinal outcomes and related "fade-out effects." The most cited report is the Head Start Evaluation, Synthesis, and Utilization Project (McKey et al., 1985), which reported immediate positive effects of Head Start followed by declining performance in subsequent years resulting in few meaningful differences between Head Start and control groups by the end of first grade. Given that family and environmental risk variables tend to remain relatively stable during the preschool and early elementary school years (Burchinal, Campbell, Bryant, Wasik, & Ramsey, 1997), it is really not surprising that early childhood program graduates begin school with the readiness skills they need but soon fall behind their more advantaged peers. It appears clear that early intervention by itself, whether in the form of Head Start or any other preschool program, is not sufficient to inoculate children against the continuing effects of environmental risk factors (Zigler & Styfco, 1994).

Assess Dynamically

To *prevent* the occurrence of reading failure and ensure school success for all children, we need to do more than simply prepare children to be ready for school. If we are to maintain the gains made by families and early childhood programs in preparing children for school, we need a dynamic, prevention-oriented, school-based assessment and intervention system designed to monitor the growth and development of children through the critical early school years. Such a system can preempt early academic and social difficulties and enable children to maintain gains and progress step-by-step toward outcomes that will result in school success (Good, Simmons, & Kame'enui, 2001).

For a prevention-oriented, school-based system of assessment to be effective, it must reliably (a) measure growth on foundational reading skills on a frequent and ongoing basis, (b) predict success or failure on criterion measures of performance (i.e., high-stakes tests), and (c) provide an instructional goal that, if met, will prevent reading failure and promote reading success. The minimum criteria for best practices in early literacy assessment to meet the requirements above are outlined in Table 1.

DYNAMIC INDICATORS OF BASIC EARLY LITERACY SKILLS

Techniques for measuring growth and development of early literacy skills in kindergarten and first grade that meet the criteria outlined in Table 1 have been developed at the University of Oregon (Kaminski & Good, 1996; Kaminski & Good, 1998). DIBELS were developed to monitor growth in the acquisition of critical early literacy skills to (a) identify children in need of intervention and (b) evaluate the effectiveness of intervention strategies. Ongoing research on DIBELS, supported by the Early Childhood Research Institute on Measuring Growth and Development

Table 1. Checklist of criteria for early literacy assessment

Yes	*No*		*Content*
☐	☐	1.	Does the assessment measure *phonological awareness* skill as a clear, explicit priority?
☐	☐	2.	Does the assessment measure *alphabetic principle* skill as a clear, explicit priority?
☐	☐	3.	Does the assessment measure *accuracy and fluency with connected text* as a clear, explicit priority?
Yes	*No*		*Practical Considerations*
☐	☐	4.	Is the assessment efficient and economical with minimal disruption of instructional time?
☐	☐	5.	Is the assessment standardized/replicable?
☐	☐	6.	Is the assessment repeatable over time with many alternate forms?
☐	☐	7.	Is the assessment simple to learn, administer, and score?
Yes	*No*		*Technical Characteristics*
☐	☐	8.	Does the assessment have evidence of reliability sufficient to be reasonably confident that low scores represent low skills needing intervention?
☐	☐	9.	Does the assessment have evidence of validity especially predicting success and difficulty achieving important reading outcomes?
☐	☐	10.	Does the assessment have evidence of sensitivity to changes in students' skills due to instruction?
Yes	*No*		*Decision-Making Utility: Individual*
☐	☐	11.	Does the assessment identify children who *need additional instructional support* to achieve reading goals?
☐	☐	12.	Does the assessment provide *instructional goals* to change first-grade reading outcomes for children at risk of reading difficulty?
☐	☐	13.	Does the assessment inform decisions about the *effectiveness of instruction* on a week-by-week, student-by-student basis?
Yes	*No*		*Decision-Making Utility: Systems*
☐	☐	14.	Does the assessment inform decisions about the effectiveness of the *core curriculum and instruction* for most children?
☐	☐	15.	Does the assessment inform decisions about the effectiveness of the *system of additional instructional support* for children at risk of reading difficulty?
☐	☐	16.	Does the assessment inform decisions about class, school, and district *year-to-year improvement* in early literacy skills and reading outcomes?

(ECRI-MGD), has generated a large database supporting the psychometric adequacy of the DIBELS (Good et al., in press). We have a clear knowledge based on the critical DIBELS benchmarks in kindergarten and first grade for successful reading outcomes. In addition, we have clear evidence of the level of skill that predicts risk. As early as fall of kindergarten, for example, we are able to predict, with a high degree of accuracy, which children will have significant difficulty learning essential literacy skills unless additional instructional support is provided. Good et al. (2001) describe the utility of DIBELS within a preventive assessment approach. The DIBELS assessment approach will be described here with respect to each of the criteria for best practice in early literacy assessment delineated in Table 1.

Content: Measuring the Foundational Skills of Beginning Reading

Converging and convincing evidence substantiates that reading competence is causally influenced by proficiency on foundational skills in beginning reading (National Reading Panel, 2000; National Research Council, 1998). We refer to the recognized and empirically validated foundational skills related to reading outcomes as the "big ideas" in beginning reading. Big ideas are skills and strategies that are prerequisite and fundamental to later reading success. They are skills that differentiate successful from less successful readers and, most important, are amenable to change through instruction (Kame'enui & Carnine, 1998; Simmons & Kame'enui, 1998). In the area of beginning reading, foundational skills include: (a) phonological awareness or the ability to hear and manipulate the sound structure of language, (b) alphabetic principle including alphabetic understanding or the mapping of print to speech and the phonological recoding of letter strings into corresponding sounds and blending stored sounds into words, and (c) accuracy and fluency with connected text or the facile and seemingly effortless recognition of words in connected text (Adams, 1990; National Reading Panel, 2000; National Research Council, 1998; Simmons & Kame'enui, 1998).

Practical Considerations

DIBELS measures have been developed to meet the practical characteristics that enable DIBELS to be used frequently and repeatedly over time to measure growth. Thus, each of the measures is brief, efficient, economical, and relatively simple to administer and score, with multiple alternate forms. Each of the measures is described below.

1. *DIBELS Onset Recognition Fluency (OnRF)* is a standardized, individually administered measure of phonological awareness that assesses a child's ability to recognize and produce the initial sound in an orally presented word (Kaminski & Good, 1998; Laimon, 1994). The examiner presents four pictures to the child, names each picture, and then asks the child to identify (i.e., point to or say) the picture that begins with the sound produced orally by the examiner. For example, the examiner says, "This is sink, cat, gloves, and hat. Which picture begins with /s/?" and the student points to the correct picture. The child is also asked to orally produce the beginning sound for an orally presented word that matches one of the given pictures. The examiner calculates the amount of time taken to identify/produce the correct sound and converts the score into the number of onsets correct in a minute. The OnRF measure takes about 3 minutes to administer and has more than 20 alternate forms to monitor progress.

2. *DIBELS Phoneme Segmentation Fluency (PSF)* is a standardized, individually administered test of phonological awareness (Kaminski & Good, 1996). The PSF measure assesses a student's ability to segment three- and four-phoneme words into their individual phonemes fluently. The PSF measure has been found to be a good predictor of later reading achievement and is intended for use with students from the winter of kindergarten to the middle of first grade (Kaminski & Good, 1996). The examiner administers the PSF task by orally presenting words of three to four phonemes. The student is asked to produce verbally the individual phonemes for each word. For example, the examiner says, "sat," and the student says /s/ /a/ /t/ to receive three possible points for the word. After the student responds, the examiner presents the next word, and the number of correct phonemes produced in 1 minute determines the final score. The PSF measure takes about 2 minutes to administer and has more than 20 alternate forms for monitoring progress.

3. *DIBELS Nonsense Word Fluency (NWF)* is a standardized, individually administered test of the alphabetic principle—including letter-sound correspondence and of the ability to blend letters into words in which letters represent their most common sounds. The student is presented an 8.5" x 11" sheet of paper with randomly ordered VC and CVC nonsense words (e.g., sig, rav, ov) and asked to produce verbally the individual letter sound of each letter or verbally produce, or read, the whole nonsense word. For example, if the stimulus word is "vaj" then the student could say /v/ /a/ /j/ or say the word "vaj" to obtain a total of three letter-sounds correct. The student is allowed 1 minute to produce as many letter-sounds as he or she can, and the final score is the number of letter-sounds produced correctly in 1 minute. Because the measure is fluency based, students receive a higher score if they are phonologically recoding the word and receive a lower score if they are providing letter sounds in isolation. The NWF measure also takes about 2 minutes to administer and has more than 20 alternate forms for monitoring progress.

4. *DIBELS Letter Naming Fluency (LNF)* is a standardized, individually administered test that provides a measure of risk (Kaminski & Good, 1996). Students are presented with upper- and lower-case letters arranged in a random order and are asked to name as many letters as they can. Students are told if they do not know a letter they will be told the letter. The student is allowed 1 minute to produce as many letter names as he or she can, and the score is the number of letters named correctly in 1 minute. Students are considered *at risk* for difficulty in achieving early literacy benchmark goals if they perform in the lowest 20% of students in their district, that is, below the 20th percentile using local district norms. Students are considered at *some risk* if they perform between the 20th and 40th percentile using local norms. Students are considered at *low risk* if they perform above the 40th percentile using local norms.

5. *Curriculum-Based Measurement (CBM) of Oral Reading Fluency (CBM ORF)* is a standardized procedure to assess accuracy and fluency with connected text. A version of CBM ORF has been published as the Test of Reading Fluency (TORF) (Children's Educational Services, 1987). The TORF is a standardized set of passages and administration procedures designed to (a) identify children who may need further intensive assessment and (b) measure growth in reading skills (Children's Educational Services, 1987, p. 1). Passages were calibrated for each grade level, and student performance is measured by having students read each of three passages aloud for 1 minute. Words omitted, substituted, and hesitations of more than 3 seconds are scored as errors. Words self-corrected within 3 seconds are scored as accurate. The median correct words per minute from the three passages is the oral reading fluency rate.

Technical Characteristics

Evidence of reliability, validity, and sensitivity for DIBELS has been investigated in a series of studies and is summarized in Table 2. Alternate-form reliability of the DIBELS measures are generally adequate and range from .65 to .93. While the level of reliability for OnRF is low (.65) with respect to standards for educational decision making (e.g., Salvia & Ysseldyke, 2001), the assessment can be repeated on multiple days using multiple alternate forms of the measure. By repeating the brief assessment five times on five different days, the resulting average score would have a reliability of .90 (Nunnally, 1978). The robust reliability of aggregate scores will be used in the decision-making model to follow. When aggregated, the reliability of the other measures ranges from .90 to .98 for the average of three repeated assessments.

The concurrent criterion-related validity of DIBELS measures with other standardized measures of early literacy skills (e.g., Metropolitan Readiness Test, Stanford Diagnostic Reading Test, Woodcock-Johnson Psycho-Educational Battery) ranges from .36 for OnRF in the beginning of Kindergarten to .81 for LNF. Predictive validity correlations with outcomes 1 year later (e.g., PSF in winter of kindergarten to CBM reading in spring of first grade) range from .36 to .82. All of the measures demonstrate sensitivity to growth over time, with a slope of 1 to 2 correct responses per minute per week.

The DIBELS measures link to CBM ORF beginning in the winter of first grade. A series of studies has confirmed the technical adequacy of CBM reading.

Table 2. Technical Adequacy of DIBELS

	Reliability			Validity		Sensitivity: Slope per week		
DIBELS measure	Single probe	Multi-probe	Slope	Concurrent	Predictive	Mean	SD	Study
OnRF	.65	.90	.35	.36,[a] .48[b]	.36,[a] .45[c]	1.34	0.81	Good et al., in progress; Laimon, 1994; Ditkowski, in progress
PSF	.88	.96	.71	.54,[b] .65[d]	.62,[d] 68[be]	1.12	1.06	Good et al., in progress; Kaminski and Good, 1992, 1996
NWF	.92	.98	.71	.59[b]	.66,[a] .82[c]	2.08	1.62	Good et al., in progress
LNF	.93	.98		.70,[a] .77[d]	.65,[a] .76,[c] .81[c]			Good et al., in progress; Kaminski and Good, 1992, 1996

Note. Multi-probe reliability based on the mean of five probes for OnRF and the mean of three probes for PSF, NWF, and LNF. Reliability of slope estimates based on weekly repeated assessments for 10–11 weeks; $p < .05$.

[a] Woodcock-Johnson Psycho-Educational Battery Total Reading cluster score.

[b] DIBELS PSF.

[c] CBM ORF.

[d] Metropolitan Readiness Test.

[e] Stanford Diagnostic Reading Test.

Test-retest reliabilities of elementary students ranged from .92 to .97; alternate-form reliability of different reading passages drawn from the same level ranged from .89 to .94 (Tindal, Marston, & Deno, 1983). Criterion-related validity studied in eight separate studies in the 1980s reported coefficients ranging from .52-.91 (Good & Jefferson, 1998).

Decision-Making Utility of DIBELS

BENCHMARKS

The benchmark goals and timelines for a trajectory of progress toward high-stakes reading outcomes are summarized in Table 3 and validated by research in different settings (Good et al., in progress; Good, Simmons, & Kame'enui, 2001). For example, OnRF provides an indicator of the child's knowledge and awareness of initial sounds in words, an aspect of phonological awareness desired by winter of kindergarten if the child is on track for reading outcomes. PSF provides an indicator of phonological awareness skills necessary by spring of kindergarten. By winter of first grade, students should display alphabetic principle skills on NWF, and by spring of first grade they should reach target levels of ORF, a measure of accuracy and fluency with connected text. By spring of second grade and spring of third grade, adequate progress on measures of ORF is necessary to be on track for high-stakes reading outcomes. The model is designed to make explicit a set of parsimonious linkages between earlier and later skills at different points in time.

In this discussion of benchmark goals, it is important to clarify that the DIBELS benchmark goals summarized in Table 3 are goals for the lowest student—not goals for the middle student or 90% of students, but goals for the lowest-achieving student in the school. Each goal is a stepping stone toward literacy. The sequence builds upon prior goals, with achievement of each goal supporting achievement of the subsequent goal (with effective instruction). The first goal is modest: for the student to be confident and fluent with the initial sounds of words, that the word "cat" starts with the sound /k/, for example. The DIBELS benchmark goals are the minimal level students need to achieve to be confident they are on track for literacy outcomes. The ultimate goal is for 100% of children within a school to achieve each benchmark.

Individual Decision Making Within an Outcomes-Driven Model

The Outcomes-Driven Model described here is based on the foundation of a problem-solving model (see Deno, 1989; Shinn, 1995) and the initial application of the problem-solving model to early literacy skills (Kaminski & Good, 1998). The Outcomes-Driven Model was developed to provide a prevention-oriented assessment and intervention decision-making

Table 3. Benchmark goals and timelines for a trajectory of progress toward high-stakes reading outcomes

Timeline	*Measure*	*Benchmark goals for the achievement of reading*	*May need intensive instructional support*
Winter, kindergarten	DIBELS OnRF	25–35	Below 10
Spring, kindergarten	DIBELS PSF	35–45	Below 10
Winter, first grade	DIBELS NWF	50	Below 30
Spring, first grade	CBM ORF	40	Below 10
Spring, second grade	CBM ORF	90	Below 50
Spring, third grade	CBM ORF	110	Below 70

system and designed to *preempt* early reading difficulty and ensure progress step-by-step toward outcomes that will result in established, adequate reading achievement. The Outcomes-Driven Model accomplishes steps to outcomes through a set of five educational decisions: (a) identifying need for support, (b) validating need for support, (c) planning support, (d) evaluating and modifying support, and (e) reviewing outcomes. A key premise of the Outcomes-Driven Model is that failure is not an option. If we promise all students they will be readers, each step must be achieved in time. We need to match the amount and type of instructional support with the needs of individual students to enable all students to reach each benchmark step. Some students will need substantial, intensive, individualized support to reach each step. Others will benefit from regular, good, large-group, classroom instruction. Some students may achieve important reading outcomes regardless of the instruction provided. The goal of the Outcomes-Driven Model is to match students with the instructional support necessary to achieve each step to reading *before* a pattern of reading difficulty and failure has been established.

IDENTIFYING NEED FOR SUPPORT

The first step in the Outcomes-Driven Model is to identify children early who *may* need additional instructional support to meet a benchmark goal. To identify need for support, a benchmark assessment using selected DIBELS and CBM probes is administered to all children in the school three times per year—at the beginning, middle, and end of the school year. The benchmark assessment is administered one-on-one with a tester and student and takes about 7 minutes per student. A team of five or six testers can assess a class of 25 students in approximately 30 minutes. The benchmark assessment provides information regarding the performance of all children in the school with respect to benchmark goals. The benchmark assessment also identifies individual students who may need additional instructional support to achieve the next benchmark goal.

Individual students needing additional instructional support can be identified using the benchmark report. The benchmark report includes a recommendation with respect to additional instructional support. A sample benchmark report to the teacher for winter of kindergarten is illustrated in Figure 2. The benchmark goal for the middle of kindergarten is 25–35 correct responses per minute on OnRF. A student who achieves 25 or above typically does not require additional instructional support, and continuation of regular, good classroom instruction is recommended with benchmark assessment (three times a year). Students who perform below 10 on DIBELS OnRF and who are low on DIBELS PSF may require intensive instructional support to achieve the end-of-kindergarten step to reading outcomes. The DIBELS LNF measure provides an additional measure of risk. Students with scores on DIBELS LNF in the lowest 20% of students in a school or district are likely to need additional instructional support. Students who score between 10 and 25 on OnRF are judged to have emerging skills. Additional instructional support and more frequent assessment to monitor growth of skills are warranted for these students.

In the class depicted in Figure 2, Joseph and Tiffany have met the middle-of-kindergarten benchmark of 25–35, and both children are beginning to acquire skill in phoneme segmentation as indicated by PSF scores of 15 and 13, respectively. Additionally, Joseph and Tiffany are performing in the low-risk range on LNF as evidenced by percentile rankings of 66 and 85. Both Joseph and Tiffany are considered to be at low risk for the development of later reading dif-

Figure 2. Sample benchmark assessment report for middle of kindergarten, with recommendation for instructional support needed to achieve next early literacy goal

	Onset Recognition Fluency			Phoneme Segmentation Fluency			Letter Naming Fluency			
Student	Score	Percentile	Initial Sound Skill Status	Score	Percentile	All Sounds Skill Status	Score	Percentile	Risk Status	Instructional Recommendations Based Primarily on PSF
T., Sandra	9	4	Deficit	1	7	Deficit	8	13	At risk	Intensive support indicated.
R., Matrix	7	2	Deficit	1	7	Deficit	11	19	At risk	Intensive support indicated.
W., Halley	14	12	Emerging	2	9	Deficit	29	46	Low risk	Strategic support.
M., Latisha	19	22	Emerging	3	11	Deficit	35	59	Low risk	Strategic support.
A., Brandon	9	4	Deficit	3	11	Deficit	24	35	Some risk	Intensive support indicated.
R., Tiffany	42	86	Established	13	31	Emerging	48	85	Low risk	Benchmark.
M., Danielle	5	1	Deficit	14	33	Emerging	21	28	Some risk	Strategic support.
M., Joseph	38	75	Established	15	35	Emerging	37	66	Low risk	Benchmark.

ficulties, and the continuation of regular, good classroom instruction with benchmark assessment at the end of kindergarten is recommended. On the other hand, Sandra, Matrix, and Brandon scored below 10 on OnRF and also scored low on PSF in the middle of kindergarten. In addition, all three students achieved percentile rank scores in the at-risk range on LNF (below 20th percentile). Based on their performance, Sandra, Matrix, and Brandon may require substantial, intensive instructional support to achieve the end-of-kindergarten benchmark goal.

Danielle also scored below 10 on OnRF on this assessment; however, her scores on PSF indicate that her phoneme segmentation skills are emerging. Her percentile rank for LNF is in the some-risk range (28th percentile). Danielle may have difficulty achieving the spring early-literacy goal, and strategic instruction and assessment may be required. Hailey and Latisha also may need strategic instruction and assessment to achieve a goal of 35–45 on PSF by spring of kindergarten.

When extremely brief measures are used to obtain an indication of skills, alternative reasons for low performance must be considered. For example, students may have a bad day, be ill, be confused by the directions, or be uncomfortable with an unfamiliar examiner rather than have an actual skill deficit. For students whose skills *may* be a concern as indicated by performance on the benchmark assessment, validation of need for instructional support is the next step.

Validating Need for Instructional Support

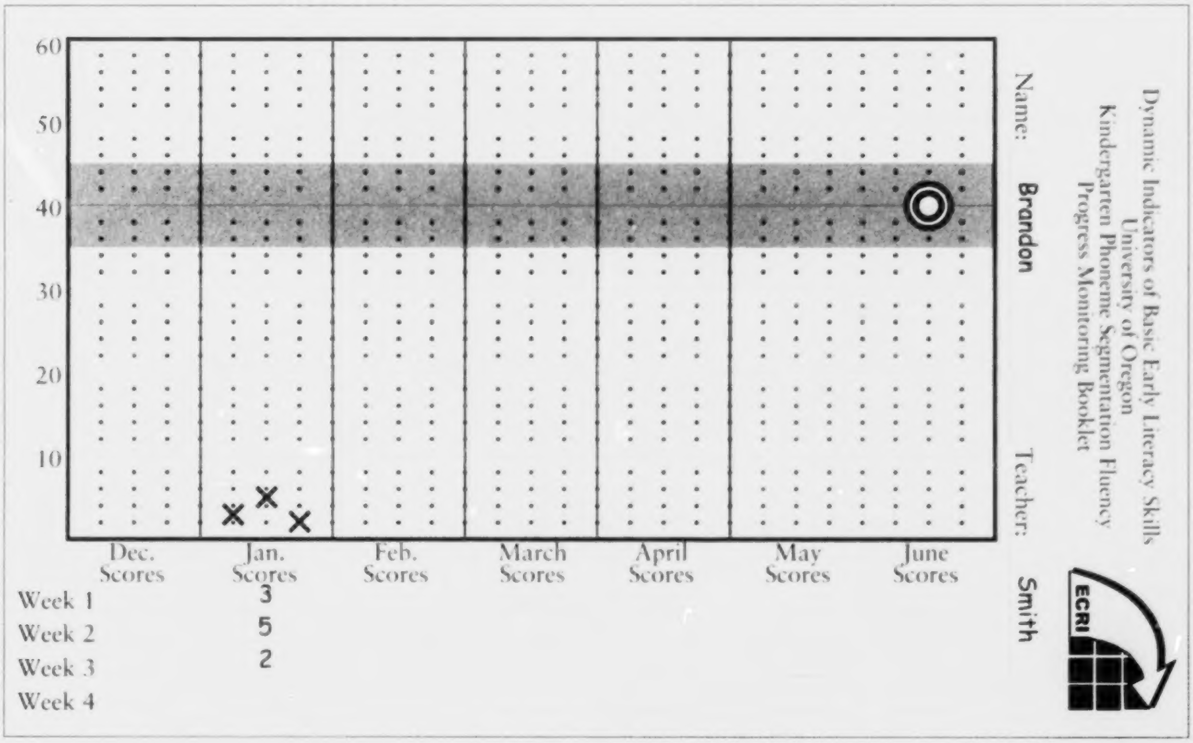
The next step in the Outcomes-Driven Model is to be reasonably confident that the student needs additional instructional support and that some other factor is not the reason for low performance. Several possible reasons might cause a student's score to be low on one sample of behavior at one point in time under one set of conditions. The student may be confused about the task, may be shy with an unfamiliar adult, may have had a bad experience on the playground before assessment, or may be recovering from an illness. In addition, we regularly encounter instances where a score was miscopied, entered incorrectly, or transposed. When considering a child's scores, it is important to consider first that the score might be inaccurate. The possibility of inaccurate scores is not unique to the DIBELS or CBM measures. Inaccurate scores are possible with any standardized assessment and may be more likely with younger children.

One important advantage of DIBELS and CBM over other standardized assessments is the ease with which a child's score can be rechecked. In the validating need for instructional support step, an examiner conducts brief repeat assessments of the target skill using alternate forms of the assessment under different conditions. The progress-monitoring booklet for each step includes alternate forms of the measure that can be used by any trained teacher to retest a child. Because assessments are each about 1 minute, and because each measure has over 20 alternate forms available, repeated measures for students of concern can be conducted with reasonable efficiency. By retesting students whose skills are of concern, we can increase our confidence that a low score is indicative of low skills rather than a bad day. Each retest examines a hypothesis about poor performance. If it seems plausible that a child was uncomfortable with an unfamiliar adult, the child can be retested with a familiar teacher or aide. If the child had a bad day or was sick, he or she can be retested another day.

A sample progress-monitoring booklet illustrating the teacher's decision that Brandon needs additional instructional support and that his initial low score was not just a bad day is illustrated in Figure 3. In the first week of January, Brandon was assessed with the rest of his school in the middle-of-kindergarten benchmark assessment (i.e., identifying need for instructional support). His scores of 9 on DIBELS OnRF and 3 on DIBELS PSF were a cause for concern for his teacher, Ms. Smith. Brandon did not meet the middle-of-kindergarten benchmark of 25–35 on OnRF, and his score of 3 on PSF indicates his phonological awareness skills are not yet emerging. Brandon's teacher wanted to make sure that his low performance on the 1-minute DIBELS measures was not simply because an unfamiliar person tested him right after the winter break. To validate the benchmark results, Ms. Smith personally retested Brandon with an alternate form of PSF before recess the following week and again with another alternate form after lunch the next week. Ms. Smith then examined Brandon's pattern of performance across the multiple assessments and concluded he was at risk for not meeting the end-of-kindergarten benchmark goal of 35–45 on DIBELS PSF and additional instructional support was warranted.

Three patterns of performance are possible on repeated assessments. First, if a child's scores are consistently low on two or three retests (five on OnRF) using different samples of behavior on different days under different conditions, the teacher can be rea-

Figure 3. Sample of repeated assessments to validate need for instructional support for Brandon



sonably confident the child's skills are low. Second, if only the initial testing is low, and the child consistently scores in the desired range on subsequent retests, the first assessment may have been inaccurate (i.e., the child was having a bad day). Third, the child may be extremely variable in performance: fine one day, but very low the next. In this case, we are alerted to other factors potentially affecting the child's performance. For example, an ear infection may negatively affect a child's hearing on some days but not others, or a child's motivation and effort may be inconsistent from one day to the next.

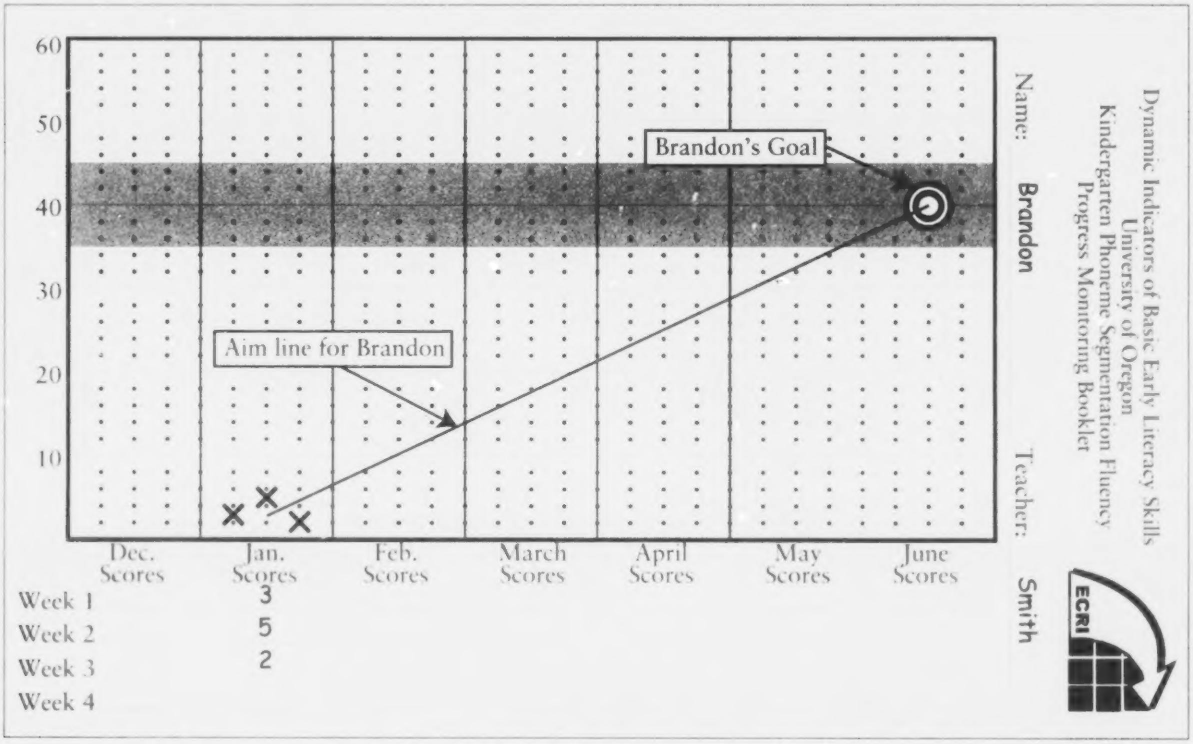
As illustrated in Figure 3, Brandon's performance on each of the retests on PSF was consistently low. Based on the repeated assessments, Brandon's teacher was confident that Brandon did have a deficit in phonological awareness and would benefit from additional instructional support to reach the next benchmark goal. The next decision-making step in the Outcomes-Driven Model is to plan instructional support for Brandon.

PLANNING INSTRUCTIONAL SUPPORT

A plan for providing additional instructional support should include (a) a clear instructional goal that will be a step to outcomes for the achievement of reading, (b) a focus on essential skills that are big ideas of early literacy and reading, (c) a plan for the amount and type of support the student is likely to need, (d) a specification of the logistics of who will teach using what instructional materials, when and where, and (e) a measurement plan to evaluate progress.

For each step in the model, a benchmark goal has been established (Table 3) and validated (Good, Simmons, & Kame'enui, 2001; Good et al., in progress). Achievement of that goal is a step to reading outcomes. An example goal is illustrated for Brandon in Figure 4. If Brandon is going to achieve the next benchmark goal of 35–45 on PSF at the end of kindergarten, then he will need to progress along the aimline illustrated in Figure 4. The aimline provides a map of expected progress to be used to monitor growth and plan instruction from week to week. The

Figure 4. Planning instructional support for Brandon: Specifying a goal and aimline for satisfactory progress



goal and systematic progress monitoring assist in focusing instructional effort on the crucial big ideas with a sense of urgency.

Research-based interventions have been developed, published, and validated to provide additional instructional support for each of the foundational early reading skills for which there is a corresponding benchmark goal. Instructional supports may be considered as falling along a continuum ranging from broad-based supports designed to build the skills of many or all children in the class (good classroom instruction) to high-intensity, individual interventions. For example, in the area of phonological awareness, the Phonemic Awareness for Children (Adams, Foorman, Lundberg, & Beeler, 1998) and Ladders to Literacy (O'Connor, Notari-Syverson, & Vadesy, 1998) curricula are available for regular classroom instruction. The Phonological Awareness Training for Reading curriculum (Torgesen & Bryant, 1994) is available for small group instruction of students who are having difficulty learning phonological awareness skills. Other instructional approaches are available and have received commendation as effective and valid.

Teachers have a variety of choices of materials to match their instructional preferences. Characteristics of additional instructional support for students needing intensive and strategic support are depicted in Table 4. In addition to curricula, other characteristics of instruction that may vary to meet the needs of individual children include time, size of group, selection of examples, and amount of practice. As long as the instructional support is sufficient for the student to progress along the aimline necessary to reach the goal, the choice of instructional curricula and strategies is appropriate. To determine if the instructional strategies are appropriate, however, evaluation is necessary. It may be necessary to modify the instructional support provided.

EVALUATING AND MODIFYING INSTRUCTIONAL SUPPORT

A key part of effective instruction is the integration of an assessment-intervention feedback loop in which

Table 4. Characteristics of Instruction for Intensive, Strategic, and Benchmark Instructional Support

Instructional characteristic	*Intensive instructional support*	*Strategic instructional support*	*Benchmark instructional support*
Frequency of progress monitoring	One per week	One every 2 weeks or one per month, depending on level of concern	Three per year: beginning, middle, and end of school year
Time allocated to instruction	Benchmark instruction, plus 20 minutes four times per week in small groups, plus home practice and support; extra sessions as needed.	Benchmark instruction plus extra sessions as needed	Embedded throughout day and 20 minutes per day, 4 days per week
Group size	Additional support in small group of about three	Additional support in small group of about five	Whole group and small group
Sample Phonological Awareness Curricula	• PATR • DI Reading Scripts • Optimize • Take Home Phonological Awareness	Mixture of intensive and benchmark curricula matching student needs	• Phonemic Awareness for Young Children • Road to the Code • Ladders to Literacy
Selection of examples	Carefully designed examples following a designed sequence of skills that match student skills and understanding	Examples designed to match student needs	Broad range of examples designed to move group
Amount of practice	30–40 responses per minute; choral responding to increase engagement and opportunities to practice; mixture of group and individual practice	Mixture of intensive and benchmark activities matching student needs	10–15 responses per minute; group and individual practice embedded in class activities

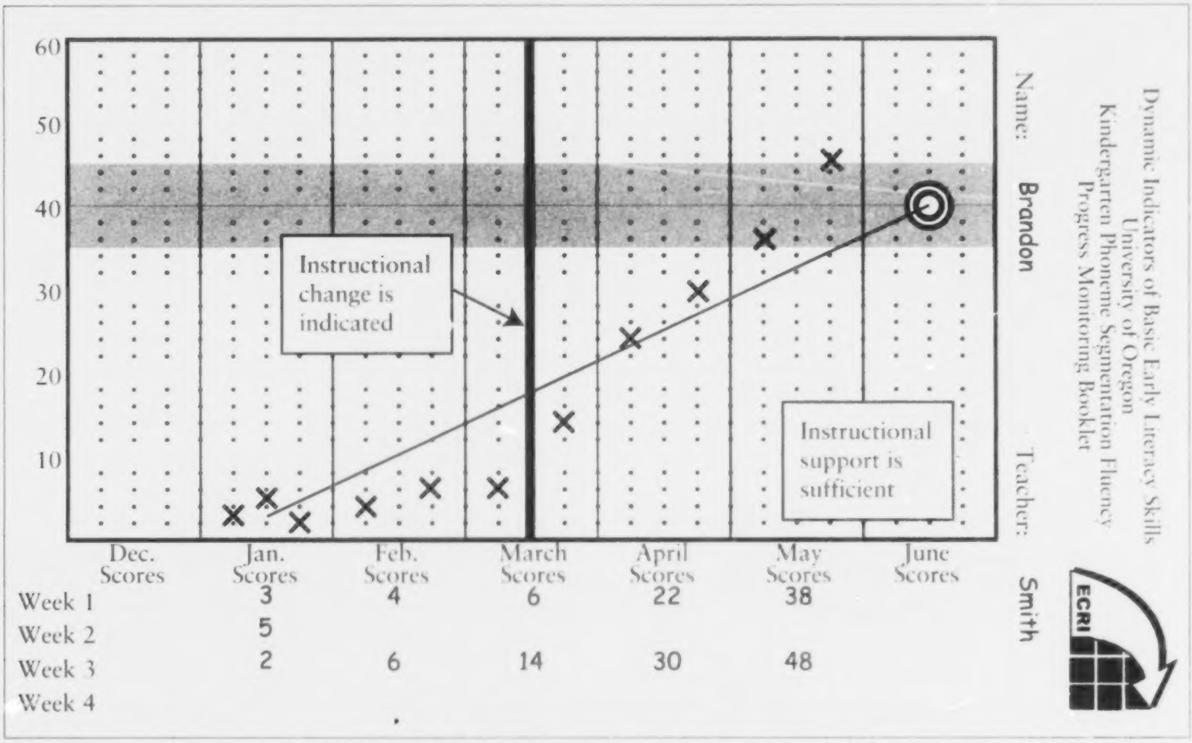
instructional support is evaluated and the instructional plan is modified based on student progress, until sufficient support is provided for the student to achieve the benchmark goal. A good plan is a powerful starting place for instruction, but an individual child's response to a particular curriculum or strategy is unpredictable. No matter how good the plan, if it is not supporting the student's progress toward the goal, it needs to be modified. The point of a formative evaluation of progress is to establish an assessment-intervention feedback loop whereby progress below the aimline triggers modifications to instruction, perhaps requiring additional time or resources or a different instructional approach incorporating more principles of effective instruction (e.g., Kame'enui & Carnine, 1998).

The first step in evaluating support is to establish a frequency of assessment to evaluate progress. For students who need substantial, intensive instructional support, weekly monitoring of progress is indicated. For students who need less support, less frequent monitoring (e.g., monthly) is sufficient. The next step is to establish decision rules to use to evaluate the data. Fuchs and colleagues recommend using a goal-oriented rule that is straightforward for teachers to understand and use (Fuchs, 1988, 1989). Student scores are plotted on a graph and compared to the aimline. When performance falls below the aimline on three consecutive points, instructional modifications are warranted (White & Haring, 1980).

Figure 5 illustrates the step of evaluating and modifying instructional support for Brandon. Because of her concern about Brandon's progress, his teacher assessed Brandon's skills bi-weekly on PSF. Using the progress-monitoring booklet for PSF, Ms. Smith administered a PSF probe to Brandon using alternate forms every other week and plotted his performance on the graph.

Small-group instructional support was begun for Brandon in the beginning of February. After 6 weeks of small group instruction, the teacher had three additional PSF scores. Brandon's performance continued consistently below the aimline. Ms. Smith decided the small group instructional support was not sufficient

Figure 5. Evaluating and modifying instructional support for Brandon



for Brandon to achieve the benchmark goal for PSF by the end of kindergarten. She then modified Brandon's instruction to provide additional modeling, examples, and practice. In the following weeks, Brandon's performance climbed above the aimline, indicating he was on track to achieve the end-of-year benchmark for phonemic segmentation. Toward the end of May, Brandon achieved the kindergarten benchmark goal on PSF.

REVIEWING OUTCOMES

In the Outcomes-Driven Model, the bottom line is achievement of essential literacy outcomes. The purpose of the reviewing-outcomes step is to review the structure of supports the school has in place to achieve outcomes at both an individual-student level and at a systems level. For *individual students* the teacher must decide if the student has achieved the benchmark and no longer requires additional instructional support. The benchmark assessment data for each benchmark goal can be used to answer this question using the same procedures as in identifying need for instructional support. For Brandon, the final data point in Figure 5 corresponds to his end-of-kindergarten benchmark score. Brandon's score of 38 in May of kindergarten indicates he has achieved the benchmark goal. Brandon will continue to be assessed in the fall, winter, and spring of first grade to ensure that he stays on track to achieve the subsequent benchmark goals at the middle and end of first grade.

Systems-Level Decision Making

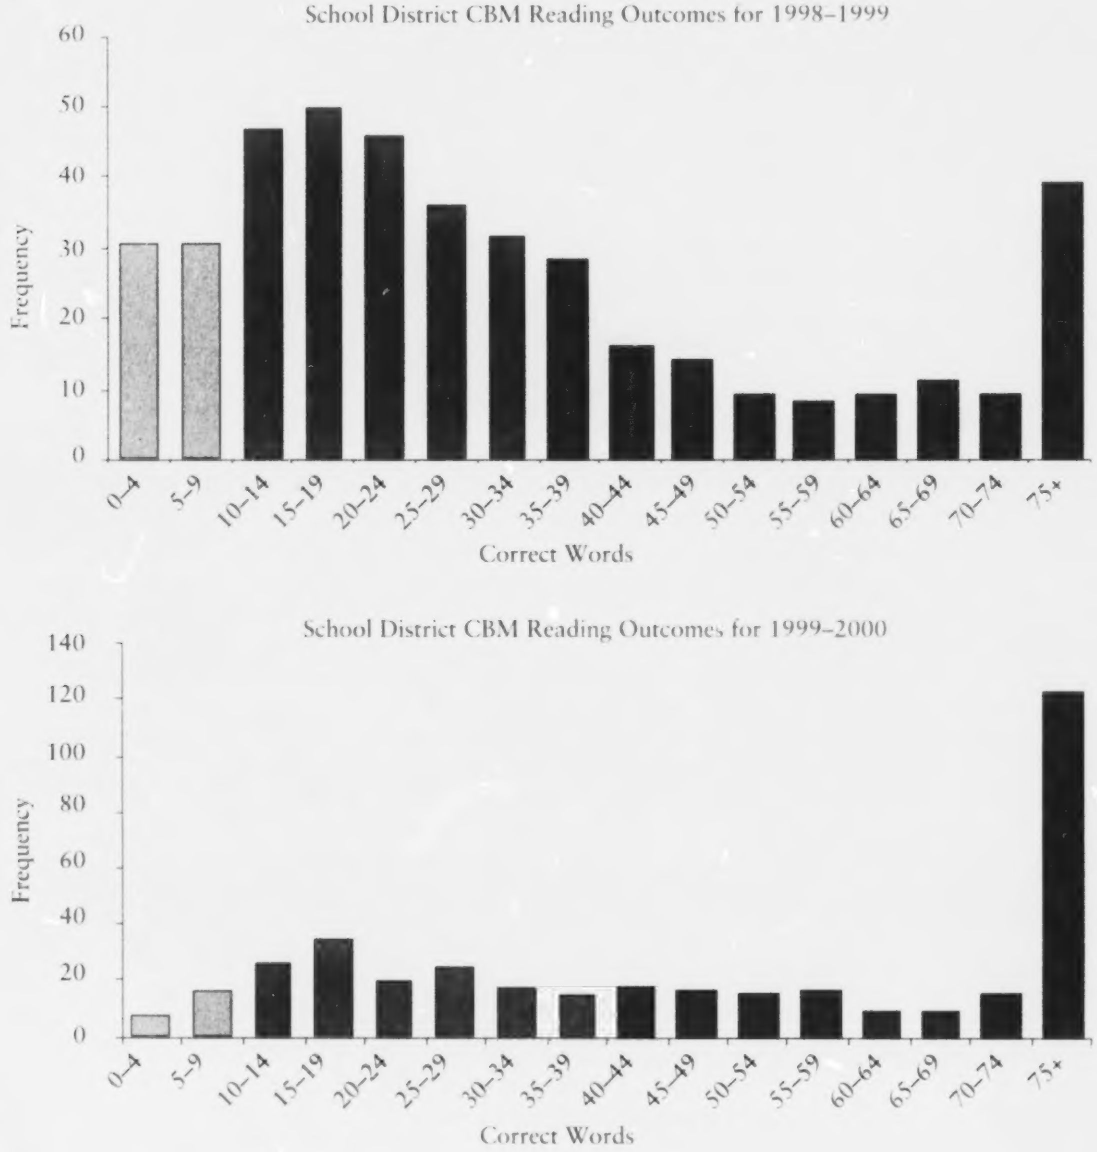
At a *systems level*, a review of outcomes and the structure of instructional supports should address the overall effectiveness of curriculum and instruction in supporting *all* children to achieve important reading outcomes. A first concern is the core curriculum and instruction that serves as the educational foundation for the school. A rough rule of thumb is that the core curriculum should support about 80% of students to achieve benchmark goals. However, some students will need additional instructional support. About 15% will need specific targeted instructional support on areas of specific difficulty. Another 5% will need very intensive, carefully designed instruction to achieve benchmark goals. The educational system should have (a) an effective core curriculum and instruction, (b) procedures to identify students who need additional instructional support, (c) a mechanism to deliver additional instructional support (time, personnel, curriculum, space), and (d) procedures to escalate the amount of instructional support if needed to achieve benchmark goals. Two sections of the DIBELS reports assist in reviewing the system of core instruction and additional instructional support to students: (a) outcomes report and (b) benchmark linkage report.

The *outcome report* assists a district in reviewing outcomes at the systems level by providing a clear, vivid, bottom line assessment of outcomes. The outcome report addresses the question, *What percent of students achieved essential reading outcomes?* A school or district should have a clear and vivid goal and should review from year to year its effectiveness in achieving the goal. A school district distribution from an outcome report is illustrated in Figure 6. On the horizontal axis are different levels of reading skills, and on the vertical axis is the number of students who achieved that level of reading skill. The solid bars represent students who achieved the reading outcome goal. The striped bars and dotted bars represent the students whose achievement was below or severely below the district goal.

For example, the district whose outcomes are illustrated in Figure 6 has the goal that all students will be able to read 40 or more words correct per minute on CBM reading passages. At the end of the 1998–1999 academic year (top of Figure 6), 28% of students in the district had achieved that goal. In the 1999–2000 academic year, the district focused considerable effort on district-wide educational reform, including (a) the use of DIBELS and CBM in an Outcomes-Driven Model, (b) review and adoption of improved core early literacy instructional curriculum in early grades, and (c) targeting at-risk children and providing additional, effective, instructional support early. At the end of the 1999–2000 academic year, the district achieved the first-grade reading outcomes illustrated in the bottom of Figure 6. The number of children achieving the reading goal had doubled, to 54%. The number of students who were reading below 10 correct words per minute was cut to less than half of the previous year, to 6%.

The school district in Figure 6 concluded it was moving in the right direction and had made real and meaningful progress toward the district goal. Further

Figure 6. First-grade reading outcomes for a school district for the 1998–1999 and the 1999–2000 academic years



improvement in outcomes was still necessary to achieve the district goal of 100% established readers at the end of first grade. The outcome report assists in keeping a focus on the bottom line but provides limited assistance in figuring out the precise step in acquisition of early literacy skills where students are experiencing difficulty, and whether the core curriculum or additional instructional support systems are in need of modification. Additional information about each step in the acquisition of reading skills is available in the benchmark linkage reports.

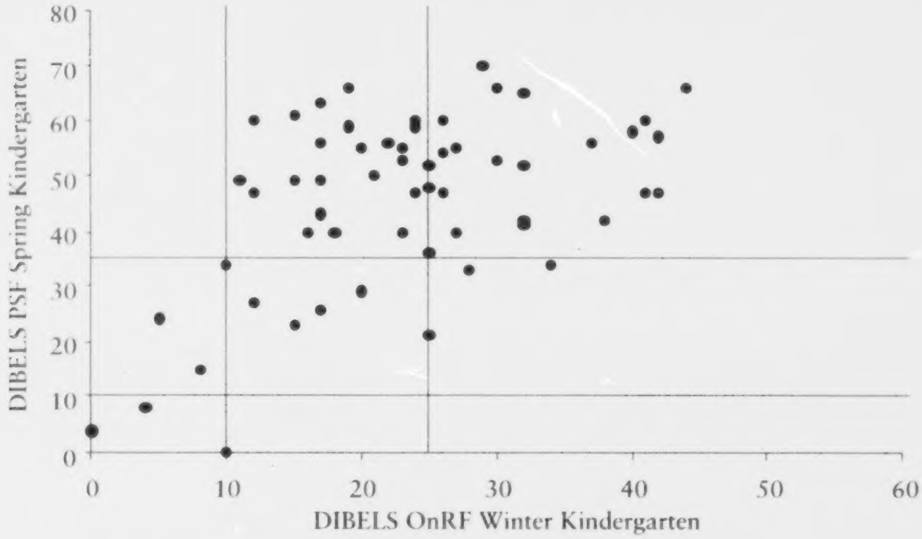
The second type of school report to assist a district in reviewing its system of instructional support is the *benchmark linkage report*. The benchmark linkage report is also provided for schools participating in the DIBELS Web (available to registered users at idea.uoregon.edu/~dibels/) data entry and reporting service. The purpose of the linkage report is to provide a picture of the connection between students achieving earlier benchmark goals and achieving later benchmark goals. The goal is to make clear to teachers the importance of each benchmark goal for *their students'* progress toward reading outcomes. If teachers want students to reach the spring-of-kindergarten goal, then one of the most important things they can do (in addition to teaching phonological awareness) is make sure all students reach the winter-of-kindergarten goal. The benchmark linkage report includes a "dot picture" showing student performance on an earlier benchmark and a later benchmark. In the sample dot picture illustrated in Figure 7, each student in a school is represented by a dot if his or her winter-of-kindergarten OnRF and spring-of-kindergarten PSF scores were available.

In addition to the dot picture, all teachers in the school receive a roster of their students and their scores, allowing teachers to associate a name and face to the dots representing their students. The vertical line at OnRF 25 indicates the winter-of-kindergarten benchmark goal of 25–35 on OnRF. Each dot on or to the right of the vertical line at OnRF 25 is a student who achieved the winter-of-kindergarten benchmark goal. The horizontal line at PSF 35 represents the spring-of-kindergarten benchmark goal of 35–45 on PSF. Each dot at or above the horizontal line at PSF 35 is a student who achieved the spring-of-kindergarten benchmark goal.

In School 1, 27 children achieved the winter-of-kindergarten benchmark goal. Of those 27 children, 24 children, or 89%, went on to achieve the spring-of-kindergarten benchmark goal on PSF. In other words, if students are strong and confident on the initial sound in words by the middle of kindergarten, then they are on track for learning all of the sounds in words. For students who meet the winter-of-kindergarten benchmark goal, their teacher teaches phonological awareness with the odds in his or her favor (89%) that their student will achieve the spring-of-kindergarten goal. Of course, meeting the winter-of-kindergarten benchmark goal is not a guarantee of continued progress. In School 1, three children (11%) who achieved the winter goal did not achieve the spring-of-kindergarten goal. Continued effort and vigilance are indicated to catch students early and provide additional instructional support if they are not making adequate progress.

Alternatively, students who have difficulty with the initial sound in words in winter of kindergarten are likely to experience difficulty mastering all phonemes in words by spring of kindergarten. In School 1, four

Figure 7. **Linkage between achieving winter-of-kindergarten OnRF benchmark goal and achieving spring-of-kindergarten PSF benchmark goal for School 1**



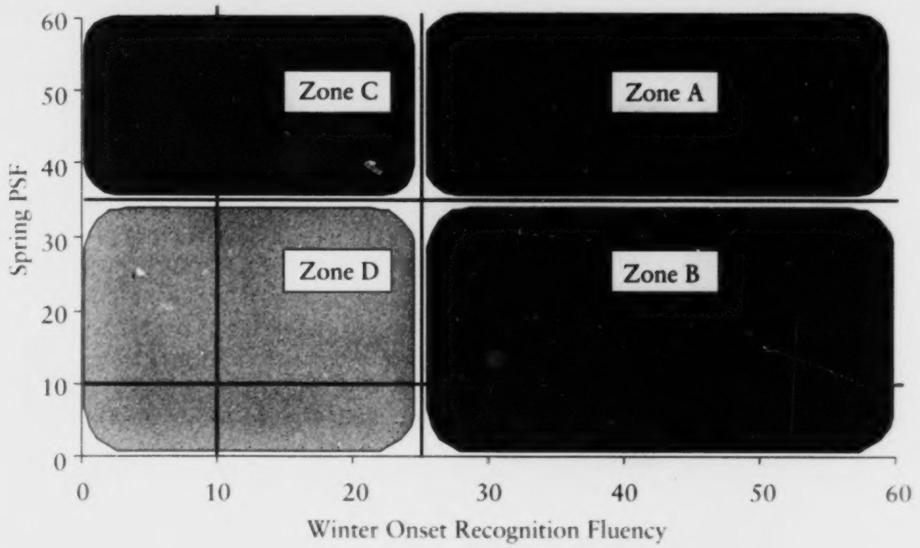
students scored less than 10 on OnRF in winter of kindergarten (i.e., their dot is to the left of the OnRF 10 vertical line), indicating significant difficulty with initial sounds in words. Of those four students, none (0%) achieved the spring-of-kindergarten PSF benchmark of 35–45. Meeting the winter benchmark goal puts the odds in the student's favor; deficit skills put the odds against achieving the next benchmark. In between the two levels (i.e., 10–25 on OnRF), a clear prediction is generally not possible.

Another purpose of the benchmark linkage reports is to provide information about the school's curriculum and instruction for a systems-level review of outcomes. When examining the linkage reports for a school, four zones of performance have instructional relevance (see Figure 8). In Figure 8, the linkage between OnRF in winter of kindergarten and PSF in spring of kindergarten is used for an illustration. A similar interpretation would be appropriate for each of the linked steps in the model. Zone A represents students who achieved the benchmark goal on an earlier skill at an earlier time (e.g., OnRF in winter of kindergarten) and who then achieved the benchmark goal on a later skill at a later time (e.g., PSF in spring of kindergarten). For each of the linkages examined, students in Zone A are progressing on a trajectory that predicts successful reading outcomes. Students who follow the Zone A pattern for each of the benchmark goals in the model of reading acquisition are on track for successful performance on high-stakes reading outcome measures. Thus, Zone A represents the desired pattern of performance and the goal of effective instruction.

The remaining three performance zones illustrated in Figure 8 provide information about students whose performance trajectories indicate weak "links" or instructional segments that may jeopardize successful reading outcomes. In some ways, instructing students toward reading outcomes is similar to running a relay race. Each leg of the race is critical to the overall outcome. If students pass from one benchmark goal to the next deficient in foundational skills, then the high-stakes outcome is jeopardized. A weak leg of the academic race can potentially be recovered with a strong compensatory later effort; however, prior research documents that the odds of this occurring decrease with time (e.g., Juel, 1988).

Students who are not in the Zone A pattern of performance have encountered some potential difficulty in their progress toward important reading outcomes. Students who achieved the earlier benchmark goal but who did not achieve the later benchmark goal would be plotted in Zone B. This pattern tells us the instructional advantage that was established ear-

Figure 8. Instructionally interpretable zones of performance for reviewing outcomes at a systems level in an Outcomes-Driven Model of the acquisition of early literacy skills and reading proficiency



lier was not sustained. Students who did not achieve the earlier benchmark goal but for whom a strong instructional effort was effective in achieving the subsequent benchmark goal are plotted in Zone C (see Figure 7 for an example). Finally, students plotted in Zone D did not achieve either the earlier or later benchmark goal. The reading progress of students in Zone D is not sufficient to make a confident prediction of reading outcomes. The likelihood of achieving reading outcomes decreases for students in the lower left quadrant of Zone D.

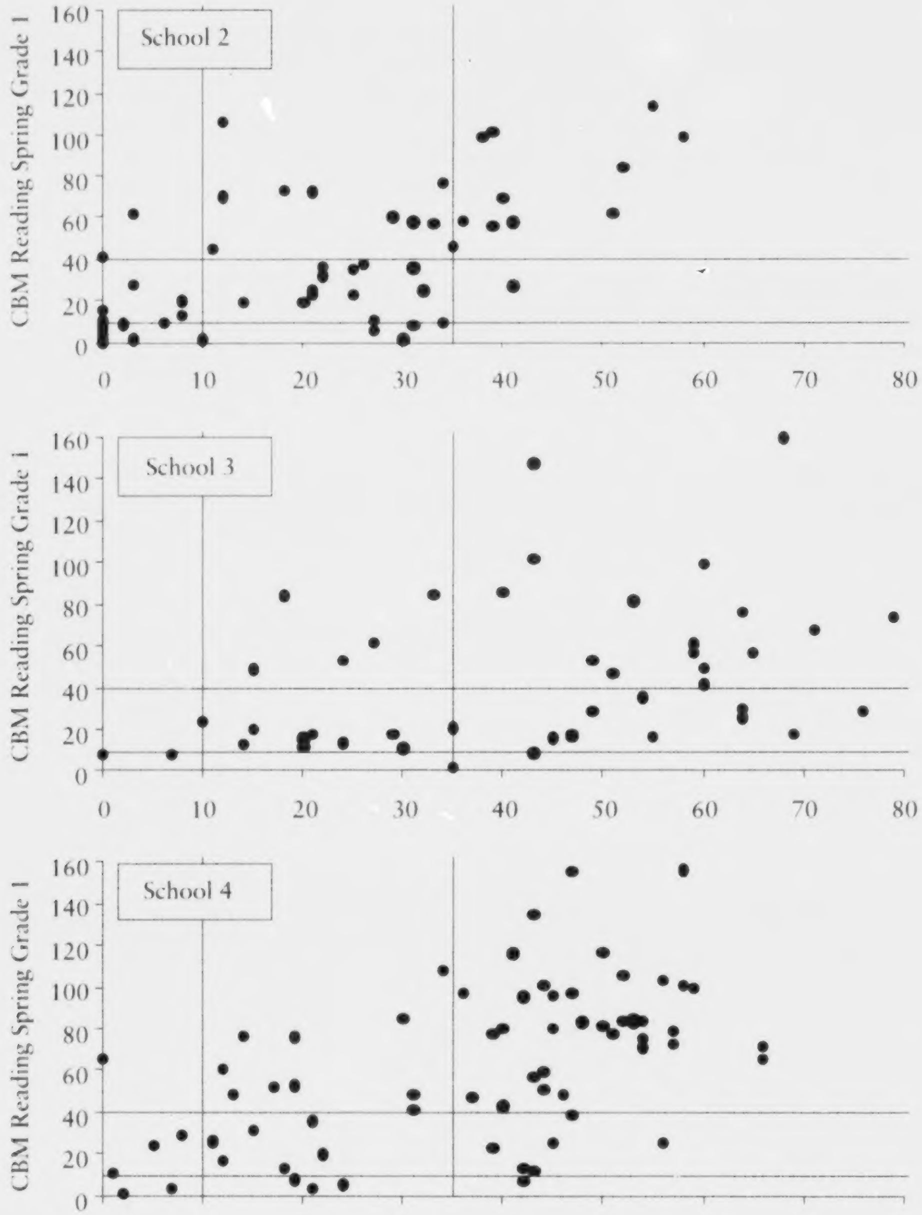
By reviewing the linkages from kindergarten through third grade, a school can identify strengths and weaknesses in their system of instructional support. If one or two students are in a zone of concern, a first question is whether they were having a bad day. Indeed, for any single student, a first hypothesis to be examined is if low performance was caused by a problem not necessarily related to low skills (e.g., uncomfortable with the tester). But, if there is a pattern of many students in a zone of concern, it is unlikely everyone was having a bad day at the same time, and more systemic explanations should be examined. A first systemic explanation to be considered is whether the integrity and standardization of DIBELS benchmark assessment procedures were sufficient to draw meaningful conclusions. Testing, scoring, and entering of scores into the DIBELS Web system should be monitored to make sure there were no points of confusion in administration and scoring procedures that would make the scores uninterpretable. However, once reasonable confidence in the scores is established, curriculum and instruction are the most important systemic factors to consider.

A striking feature of the DIBELS benchmark linkage reports is the school-to-school consistency with which meeting the earlier benchmark increases the odds of achieving the next benchmark. Equally striking are the school-to-school differences in the pattern of linkage from earlier to later benchmarks. Examining zones of performance in the linkage reports allows a review of outcomes with respect to: (a) the quality, focus, and intensity of the core instruction and curriculum and the system for providing additional instructional support *prior to* the first benchmark and (b) the quality, focus, and intensity of the core instruction and curriculum and system for providing additional instructional support *between* the first and second benchmark.

Each linkage between achievement of an earlier benchmark goal and achievement of a later benchmark goal can be examined in the same manner. For example, the linkage between spring-of-kindergarten PSF goal and the spring-of-first grade CBM reading goal is compared for three schools in Figure 9. Several important characteristics of each school's early literacy instruction and curriculum are apparent. First, many students (61%) in School 2 are not achieving the desired first-grade reading outcome. This is a clear signal that the school should examine its instruction and curriculum to identify ways to improve reading outcomes. Overall, the most students in School 2 were found in Zone D, indicating that they had not achieved either the spring-of-kindergarten goal or the first-grade reading goal. The reading growth and development of these students will be a serious concern for the school as the students move through subsequent grades (Juel, 1988, Good, Simmons, & Smith, 1998). The large number of students in Zone D is a signal the core kindergarten instruction and curriculum are not effective in supporting students to achieve the kindergarten goal, and is the initial cause of poor reading outcomes in first grade. For those students who achieved the kindergarten benchmark goal, the core first-grade curriculum and instruction were effective in supporting most students (92%) to achieve the first-grade goal. In other words, given students achieved benchmark in spring of kindergarten, the conditional percent of children who achieved the first-grade benchmark goal was 92%. Therefore, an important change for School 2 is to revise the core kindergarten curriculum and instruction to focus on phonological awareness skills and support all students to achieve the kindergarten benchmark goal in phonological awareness.

In School 3, the core kindergarten phonological awareness curriculum and instruction are more effective than School 2 in supporting most students (63%) to achieve the spring-of-kindergarten PSF goal. However, School 2 still needs a system to identify children who may need additional instructional support to achieve the goal and a system to provide that additional support. In addition, only half (55%) of the students who achieved the kindergarten PSF goal achieved the spring-of-first-grade reading goal. First-grade core curriculum and instruction must be reviewed to determine if more effective instruction or curriculum options are available.

Figure 9. Comparison of three schools' linkage reports for spring-of-kindergarten PSF and spring-of-first-grade CBM reading



In School 4, the most frequently occurring pattern of performance is Zone A (52%), with most students making satisfactory progress toward important reading outcomes. However, a substantial number of students are still not achieving the spring-of-kindergarten PSF goal in phonological awareness and the spring-of-first-grade CBM reading goal. Students who do not achieve reading goals in first grade are

707

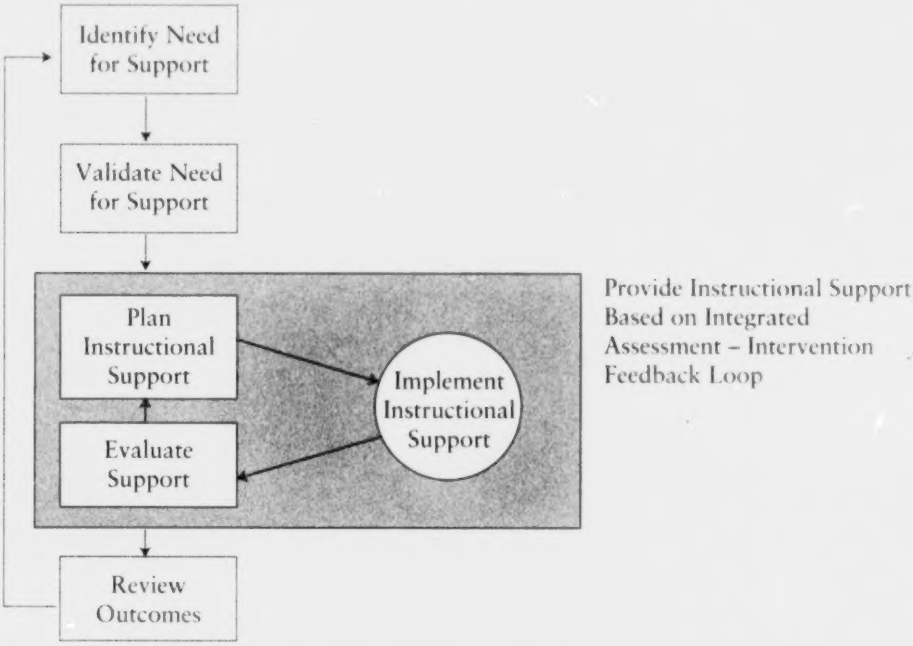
likely to continue experiencing reading difficulty (Good, Simmons, & Smith, 1998) and may require remedial or special education services during their school career. School 4 can benefit from improving its system for providing additional instructional support by identifying early those children who need additional instructional support, and by providing additional instructional support sufficient for all children (100%) to achieve early literacy benchmark goals.

DECISION LOOPS IN THE OUTCOMES-DRIVEN MODEL

The Outcomes-Driven Model is intended to be a continuous, recursive model with three primary decision loops. Completion of one cycle of a loop is intended to provide information to improve and refine the next iteration of the loop. The circular aspect of the Outcomes-Driven Model is depicted in Figure 10. The first decision loop is the assessment-intervention feedback loop described in the planning instructional support and evaluating and modifying instructional support sections. All too often assessment and intervention are treated as separate and unrelated activities. A premise of the Outcomes-Driven Model is that effective instruction incorporates an integrated, ongoing assessment-interaction feedback loop. Based on the student's progress toward an important goal, the instructional plan is changed, the implementation of instructional support is changed, the changes are evaluated, and the instructional plan is modified accordingly. The assessment-intervention feedback loop is satisfied when the student is making adequate progress toward the goal.

The second decision loop in the Outcomes-Driven Model is from one benchmark goal to the next for individual students. In the beginning of kindergarten, students who may need additional instructional support are identified, and sufficient instructional support is provided for the students to achieve the mid-kindergarten goal. The mid-kindergarten benchmark assessment of all students provides a basis to review outcomes of the instructional support provided and to identify students who may need additional support to achieve the end-of-kindergarten benchmark goal. In turn, the end-of-kindergarten benchmark assessment provides a basis to review outcomes and identify students who may need additional

Figure 10. Continuous feedback loops within an Outcomes Driven Model



Identify Need for Support
Validate Need for Support
Plan Instructional Support

Evaluate Support
Review Outcomes
Provide Instructional Support Based on Integrated Assessment – Intervention Feedback Loop

instructional support to achieve the mid-first-grade goal, and so on. The completion of each step toward literacy outcomes is the beginning of the next cycle of the Outcomes-Driven Model.

The third decision loop in the Outcomes-Driven Model is from year to year as outcomes of the instructional support system are reviewed and the system is thereby modified. This third decision loop is described in the section on reviewing outcomes at the systems level. Based on the review of benchmark linkage reports, for example, the school may decide a stronger focus on and more effort invested in early phonological awareness instruction, including initial sounds in words, is desirable in the first part of kindergarten. The school's early-literacy team might decide to adopt Ladders to Literacy (O'Connor et al, 1998) as a part of the core, early-kindergarten curriculum. Ladders to Literacy is an activity-based kindergarten curriculum that focuses on print awareness, oral language, and phonological awareness skills. The following year, the mid-kindergarten outcomes should be reviewed and compared with outcomes of prior years. Not all changes in curriculum and instruction are improvements. Educational reforms that improve outcomes and achieve goal levels should be maintained, reforms that improve outcomes but not enough to achieve goal levels should be strengthened, and reforms that decrease outcomes should be abandoned. It is reasonable to anticipate that achieving life-changing goals may be a multiyear process of improvement and refinement, but progress toward outcome goals should be apparent. It is not reasonable to take 7–10 years to abandon ineffective practices.

SUMMARY

This chapter has described best practice in assessment of early literacy skills using DIBELS and Curriculum-Based Measurement Reading within an Outcomes-Driven Model of educational decision making. The model is prevention-oriented and is designed to preempt reading difficulties and support all children to achieve adequate reading outcomes by the end of third grade. The model incorporates conceptual foundations regarding crucial early literacy skills for assessment and instruction and is focused on empirically validated outcomes for each early literacy skill. The model builds on reliable and valid measures of essential early literacy skills (DIBELS) to be used to document growth toward outcomes, as well as a set of steps for using the data generated by the measures at both the individual and systems levels.

The bottom line in the Outcomes-Driven Model is the achievement of crucial literacy outcomes for both individual students and systems at the classroom, school, and school district levels. The outcomes drive the decisions. If outcomes for individual children and/or groups of children are adequate, then the instruction and curricula are deemed to be adequate. However, if outcomes are not adequate, then a change is warranted. Changes that increase outcomes are maintained; changes that decrease outcomes are abandoned. Because data are collected on an ongoing basis documenting growth toward important benchmark skills, instructional and or curricular modifications can be made in a timely fashion to ensure all children achieve the goal of becoming established readers by the end of grade 3.

46 Best Practices in Early Literacy Skills

Ann Casey
Minneapolis Public Schools
Kathryn Howe
St. Croix River Education District

OVERVIEW

Reading is likely the most important skill educators can impart to their pupils. Yet, large numbers of students are experiencing difficulty in mastering this most basic skill. As many as 20% of elementary children have trouble learning to read (Shaywitz, Shaywitz, Fletcher, & Escobar, 1990), and as many as 60–70% of African-American, Latino, and English language learners experience reading difficulties (Moats, 1999; Snow, Burns, & Griffin, 1998). For children who live in poverty, the problem of learning to read well enough to comprehend content areas is exacerbated. With the recent emphasis on statewide accountability systems, this concern has become even more pronounced, especially in light of students who are unable to pass basic competency exams. Why are these students failing? Why have we been stymied in our ability to solve this problem? Clearly, there is urgency to the problem of reading failure. However, we will argue that this is a solvable problem if our resources are used wisely.

Unfortunately, the ongoing disagreement about how to teach reading has resulted in classroom practices that are often far removed from what the research literature supports as necessary components for an effective reading program. During the 1980s and into the 1990s there seemed to be a dichotomy between those who advocated teaching phonics and those who believed a whole language approach was best. However, this debate can be traced back at least as far as 1967 when Jean Chall published her first edition of *Learning to Read: The Great Debate.* Without reiterating that debate here, it is safe to say that most educators today tout a more "balanced literacy" approach. The balance must include, however, a code-emphasis (phonics) in beginning reading instruction and also include meaningful, interesting text.

During this same time period, considerable research was being published on the development of reading skills. Now, there is a preponderance of evidence about how reading evolves, why some children have more trouble than others, and what curriculum and instruction can remedy this situation. Unfortunately, pre-service teacher education does not necessarily prepare one to adequately address the needs of the students. And even when teachers have been well prepared, they often are not given the instructional tools and curriculum that will provide practice in the skills their students need most. Thus, part of the problem is that both teacher preparation programs and curriculum materials have not kept abreast of what current research identifies as the most effective methods to teach reading.

In the sections that follow, we will discuss important prerequisite skills for literacy, and the importance of identification and early intervention of at-risk learners. In addition, we will address specific instructional strategies as well as system-level issues such as curriculum adoption, service delivery, staff development and advocacy. School psychologists can use this information to have a significant impact on the early literacy practices that occur in elementary schools.

BASIC CONSIDERATIONS: WHAT ARE EARLY LITERACY SKILLS?

Language ability is one of the most important precursors to learning to read. The development of language and vocabulary is foundational and prerequisite to literacy development. Hart and Risley (1995) in their important study of parent-child verbal interaction patterns found vast differences in language development between middle class children and children from less advantaged backgrounds. Those differences can be attributed to tremendous differences in the amount and kind of talking in which these families engage. By the time children enter kindergarten at age 5, the trajectories for literacy development are already well developed. Many middle class children have had hundreds of hours of story book reading that has provided them the opportunity to expand their vocabularies, develop concepts of print (the knowledge that words we say are represented in print, and that words are made of letters, read from left to right, etc.), develop phonemic awareness (the knowledge that words are composed of individual sounds), as well as develop positive attitudes for reading in general. In sharp contrast, many children from less advantaged backgrounds may have had little if any exposure to books and fewer opportunities to converse with adults. Thus, the gap between the haves and have-nots in the skills necessary to develop literacy is large upon entering school, and only grows larger without significant explicit instructional intervention.

In the Beginning School Study, Entwisle, Alexander, and Olson (1997) found that rich and poor children learn equivalent amounts during the school year. However, children from middle class families learned more during the vacation periods while poor children's skills declined during vacations. Thus, the gap that existed on the first day of kindergarten is only exacerbated over time. Presumably, during vacation periods, advantaged children go to camp, take family vacations, visit museums and libraries, and generally have numerous enriching experiences, which contribute to expanded language and cognitive skills, while poor children may have none of those experiences. While encouraging to teachers who work in high poverty schools since it is validation of their efforts in teaching, it suggests that without significant early intervention, the learning gap will not be decreased.

Without good language development experiences, students enter school without a particular skill necessary for literacy development: phonological awareness. Phonological awareness is the knowledge that the words we speak are made of individual sounds and the ability to detect and manipulate these sounds (Blachman, 1991; Wagner & Torgenson, 1987). This is strictly an auditory skill without the visual representation of sounds (letters). Phonological awareness is a necessary although not sufficient skill for the development of reading (Adams, 1990a; Smith, Simmons, & Kame'enui, 2000). For skilled reading to develop, there are three important concepts or "big ideas" necessary for beginning reading instruction to be successful. These big ideas are (a) phonological awareness, (b) alphabetic understanding, and (c) automaticity with the code or fluency (Baker, Kame'enui, Simmons, & Stahl, 1994).

The research literature in support of those three areas as foundational for reading success is large. In particular, there are a number of intervention studies demonstrating a direct relationship between training in phonological awareness and reading acquisition (Adams, 1990a; Ball & Blachman, 1991; Cunningham, 1990; Lundberg, Frost, & Peterson, 1988). Alphabetic understanding is the idea that sounds are represented by letters (phoneme-grapheme relationship) and that those letters can be blended to form words. Children who have not had considerable exposure to print will not know what letters are and that they provide the key (code) to reading. This is something they need to be explicitly taught. Automaticity is perhaps less well understood but a necessary component to fluent reading. Clearly, the ability to rapidly decode letters into sounds and then words is the foundation of good reading skill. Without this ability, comprehension cannot fully develop for a number of reasons. When a student's excess attention is devoted to decoding, less attention can be committed to comprehension. Further, less fluent readers read fewer words, thereby decreasing their exposure to the entire story, which also limits comprehension.

Explicit instruction in phonological awareness, alphabetic understanding, and fluency building can reduce the gap that exists and grows in early literacy skills as children enter kindergarten and move through the primary grades. The issue then becomes which children need the explicit instruction. This will be discussed further in the assessment section.

It is important to note here that those prerequisite skills are necessary for any student who may be deficient in them, and not just children from disadvantaged circumstances. In the past, many reading problems were viewed as visual processing problems. However, the research literature today suggests that the vast majority of reading problems can be attributed to phonological processing deficits, rapid naming speed deficits, or both, which has been labeled the "double-deficit" (Wolf, 1999). Those twin deficits are similar to the "big ideas" mentioned above. Phonemic awareness is a-subskill of phonological processing. Rapid naming speed deficits are an indicator of problems in automaticity or fluency in decoding. These children also need explicit instructional intervention in early literacy skills. As Stanovich (1994) concluded, "That direct instruction in alphabetic coding facilitates early reading instruction is one of the most well-established conclusions in all of behavioral science"(p.285).

BEST PRACTICES

Assessment of Early Literacy Skills

Unfortunately, there are still many who believe that it is developmentally inappropriate to push reading on young children and that they will learn to read when they are ready. This belief, while well intended, is misguided and contributes to lack of early identification and intervention for children who are at-risk for reading difficulties. The International Reading Association and the National Association for the Education of Young Children (1998) issued a joint position statement on developmentally appropriate practice as it relates to reading and writing and clarified that for reading success we must start early. The National Institute of Child Health and Human Development (NICHD) had an even stronger caveat. "The concept of *developmentally appropriate* should not suggest delaying intervention, but using appropriate instructional strategies at an early age—especially in kindergarten" (Grossen, 1999, p. 5). If we had mandatory preschool education, this identification process could begin even earlier. Until such time when preschool education is more prevalent, we clearly have the appropriate tools for identification of at-risk students when they enter kindergarten. Kindergarten students identified with deficits in prerequisite literacy skills can then be provided the explicit instruction they need. If students are going to be fluent readers by third grade, then they need to be reading by the end of first grade, and in order to be reading by the end of first grade they need to work toward mastery of the foundational skills of phonological awareness, alphabetic understanding, and automaticity during their kindergarten year. To avert the Matthew effect (Stanovich, 1986), in which good readers become better readers because they read, and poor readers become worse readers because they do not read, intervention must start early.

A number of assessment tools now exist for the assessment of early literacy skills. Generally, there are two purposes for the assessment of early literacy skills: (a) identification of students at-risk for reading failure and (b) progress monitoring of students receiving intervention in early literacy skills. While there are commercially available measures, the focus of this discussion will be on other easily accessible measures. Yopp (1995) provided one of the first commonly available measures for identifying students with phonological awareness deficits. She developed a phonemic segmentation test, which was published in the *Reading Teacher*, and made it available to a wide audience. This measure is useful and continues to be widely used, although it measures just one of the several categories of phonological awareness. Adams (1990a) identifies five categories: rhyming, comparing and contrasting sounds, blending, segmenting, and manipulating phonemes. In designing a kindergarten/first-grade screening measure, however, most would agree that a segmentation test by itself would not be adequate and that other areas of early literacy should also be assessed. Further, in the fall of kindergarten, a segmenting task would be too difficult for many students, and therefore not discriminate well among those in need of intervention.

These additional areas might include letter names and letter sounds as well as some measure of print concepts. While knowing letter names does not directly translate to learning the code for reading, rapid letter naming (or letter naming fluency) is a measure of automaticity (Adams, 1990a) and likely results from repeated practice in phonological awareness and alphabetic understanding (Baker, et. al., 1994). Wolf, Bally, and Morris (1986, as cited in Wolf, 1999) found notable differences among entering kindergarten students in letter naming fluency. Further, they found that older dyslexic readers have significant deficits in letter naming fluency when compared to nondisabled readers. Thus, measuring one's ability to rapidly produce letter names is thought to be a good indicator of risk for reading failure, and a low score warrants further investigation of other early literacy skills.

The ability to produce letter sounds directly relates to sounding out words necessary for fluent reading to occur. Thus, students identified as knowing few letter sounds need direct instruction in letter sounds and the blending of letter sounds. For more in-depth assessment, one can assess a child's ability to manipulate speech sounds. The following tasks are purely auditory; therefore, we refer to speech rather than letter sounds. For example, the examiner says "Top. Take away the /t/ sound and add a /c/ sound." A phoneme deletion task requires skills such as, "Say *bat* without the /b/ sound." An oddity task is one where several words are said to the child (three that start with the same sound and one that does not), and the child is asked then to identify the word that has a different beginning sound.

Print concepts are the general understanding of how print is used and consist of tasks such as asking children to identify the front of the book, identifying the place where one begins reading, or pointing to a word. The California Reading and Literature Project has developed a Concepts of Print Survey (Adams & Treadway, 2000), although one can informally assess print concepts. Since many schools now use some type of kindergarten screening instrument, it is important that those screening measures include items that assess both print concepts and knowledge of letters and sounds. Together those skills will help identify students at risk for reading failure so they can be provided with the necessary intervention they need.

Since such assessment has high stakes (without early identification more children will likely fail to learn to read), those measures need to have a high degree of reliability and validity. Perhaps the most comprehensive assessment in this area is the Dynamic Indicators of Basic Early Literacy Skills (DIBELS). The DIBELS consist of four measures that encompass both rate and skill: (a) phoneme segmentation (total number of segments produced in 1 minute; e.g., cat = /c/, /a/, /t/), (b) onset recognition fluency (number of pictures identified correctly in 1 minute; e.g., which picture begins with the /m/ sound), (c) letter naming fluency (number of letters named from a sheet in 1 minute), and (d) nonsense word fluency (number of letter sounds in CVC nonsense words blended correctly in 1 minute). The DIBELS have strong evidence of both reliability and validity (Cornachione & Wolter, 2000; Kaminisky, 2000; Kaminsky & Good, 1996). For more information about DIBELS, refer to their homepage at http://idea.uoregon.edu/~dibels/.

The DIBELS can be viewed as a downward extension of oral reading fluency measures such as those advocated by Deno (1989) and colleagues. Initially, the University of Oregon researchers were looking for one simple measure that could be used as an indicator of risk; however, they found there is a progression of skills development with onset recognition mastered before segmentation, and segmentation mastered prior to nonsense word fluency (Kaminsky, 2000). Once students have mastered nonsense word fluency or the ability to blend sounds, they should be reading, and progress monitoring can switch to Curriculum-Based Measurement (CBM; words read correctly in 1 minute). Stated another way, using CBM as your only assessment in first grade initially would result in a floor effect where the majority of first graders could not read or read very few words. However, by the end of first grade, CBM will differentiate students, but then precious time has been lost for intervention for the students who are not yet reading.

On the basis of the data collected, University of Oregon researchers have established kindergarten and first-grade benchmark goals by using DIBELS measures (Kaminisky, 2000). If these benchmarks are achieved, then there is a higher probability that the goal of successful reading by the end of first grade will be met. These benchmarks are as follows:

1. 25–35 correct per minute (cpm) on Onset Recognition Fluency by winter of kindergarten

2. 35–45 cpm on Phoneme Segmentation Fluency by spring of kindergarten

3. 40 cpm on Nonsense Word Fluency by winter of first grade
4. 40–60 cpm on reading CBM by spring of first grade

In addition to those benchmarks, Letter Naming Fluency is a general risk indicator and should be administered in the fall to both kindergarten and first-grade students.

The DIBELS provides a system for assessing and identifying students early who are at-risk for reading failure. Students who need support can be identified early and be provided with the amount and kind of support they need for those foundational skills to develop.

Curriculum and Instructional Interventions

The purpose of teaching students to read is to ensure they have access to the wonderful world of literature, to enhance their education, and to use reading in their daily lives. To read well, students have to process every word on every page with such speed and lack of effort that their attention is freed to understand the vocabulary and concepts in the text. The ability to sound out new words accounts for about 80% of the variance in first-grade comprehension, and continues to be a major factor in text comprehension as students progress through the grades (Foorman et al., 1997). Most young children comprehend vocabulary, semantics, and syntax at a much higher level than they are able to recognize words (Beck & Juel, 1995). The job of early literacy instruction, then, is to teach children to decode so their skill at recognizing printed words catches up to their skill at understanding spoken words. Although both decoding and comprehension skills must be developed, decoding skills take a top priority in the early years.

There appears to be a tight timeline during which beginning reading skills must be mastered. In fact, evidence is amassing that suggests that students who are not established readers by the end of the primary grades have only a slight chance of ever being competent readers (Juel, 1988; Lyon, 1998). Happily, research is converging on the elements that must be in place in early reading instruction. The convergence is so strong, in fact, that we can now say that if we combine research-based elements of instruction, 90–95% of our current poor readers can become average readers (Lyon, 1998). This is extraordinarily good news! It is also a major challenge.

Once the child arrives in kindergarten, we are working against the "tyranny of time" in which intervening early is our only opportunity to reduce achievement gaps (Kame'enui, 1993). Kindergarten and first-grade teachers and parents have less than 2 years to ensure that the student becomes a reader by the end of first grade. The second-grade teacher is in the important safety net position. We know the most important thing we can do is to give the student the skill to identify words. Weakness in decoding skills may be the most common and most serious source of reading difficulty (Adams, 1990b).

INSTRUCTIONAL DESIGN

Teaching children beginning reading skills so they master and retain the skills requires combining carefully sequenced content with excellent instructional design. We need to be extremely specific and redundant about instruction in order to reach the 30–40% of children who have not been learning to read in recent decades. See Kame'enui & Carnine (1998) for a thorough discussion of validated features of instructional design.

Unfortunately, most of the basal reading curricula currently in our schools neither use research-based design principles nor present the research-based sequence of skills that children need to master to learn to read. It is imperative, therefore, that school psychologists understand how reading instruction must proceed so that deficiencies in reading programs can be compensated for or, better yet, more adequate reading programs can be adopted.

ESSENTIAL COMPONENTS OF EARLY READING INSTRUCTION

For this discussion the three "big ideas" in beginning reading—Phonemic Awareness, Alphabetic Understanding, and Fluency with the Code—will be broken down even further into seven components: (a) phonemic awareness, (b) letter/sound correspondence (the grapheme, phoneme connection), (c) regular word blending (blending two or more letter sounds to make a word), (d) reading in connected text (reading words in passages to gain meaning), (e) irregular word identification (reading words that do not conform to phonetic patterns, or reading words with phonetic patterns that have not been taught yet), (f) advanced word identification (reading words with more complex phonetic constructions such as CVCe and vowel team words), and (g) fluency in reading (the ability to read accurately and quickly). Those components are stepping stones in the journey from non-reading to reading. They form a map that allows teachers to look at individual students and assess where they are on the continuum and which instruction would be most appropriate for them at which time.

Phonemic Awareness. Again, phonemic awareness is the awareness of the sounds of language and the ability to manipulate those sounds. Between the beginning of kindergarten and the end of first grade, children must master the following Phonemic Awareness skills:

1. Group words with similar and dissimilar sounds (mat, mug, sun)
2. Blend and split syllables (/f/ oot), (onset rime)
3. Blend sounds into words (/m/a/n/ = man)
4. Isolate first sounds in words (rose)
5. Segment words as a sequence of sounds (fish has three sounds: /f/i/sh/)
6. Detect and manipulate sounds within words (take /s/ from sun, add /r/ to make run)

A child is in good position for formal reading instruction when, given a series of dictated three-sound words such as "dog," the child can respond to each with 35–45 correct word segments per minute (Kaminsky, 2000).

A series of teaching formats will help students gain these skills. For example:

1. "We're going to play a say-the-word game. I'll say a word slowly, and then you say the word fast."
2. Listen. (Pause)."iiiiffff. What word? (signal)."
3. Teacher repeats step 2 with four more words: sat, Sid, am, fit.
4. Teacher repeats the set of words until students can respond correctly to all the words, making no errors.

See Carnine, Silbert, and Kame'enui (1997, pp. 62-69) for further discussion and more teaching formats.

Several excellent curricula have been developed to help kindergarten and first-grade teachers teach Phonemic Awareness skills. Annotated in this chapter are Adams, Foorman, Lundberg, and Beeler (1997). Also see O'Conner, Notari-Syverson, and Vadsky (1998). Ball and Blachman (1991) present a powerful say-it-and-move-it phonemic awareness activity.

Letter-Sound Correspondence. By the end of kindergarten the child who is well poised to move into reading can pronounce 40–50 correct letter sounds in 1 minute (E. J. Kame'enui & D. C. Simmons, personal communication). The basic instructional format for teaching letter sounds is as follows:

1. "Listen. I'll point to this letter and I'll say the sound. I'll keep saying the sound as long as I touch it. /aaa/." (Model)
2. "Say the sound with me: /aaa/." (Lead)
3. "Say the sounds yourself." (Test)

Once students can identify the sound of the letter on two successive trials, include the new letter-sound correspondence with 6–8 other known sounds. When the student can identify 4–6 letter-sound correspondences in 2 seconds, include those letters in single-syllable, CVC, decodable words (Carnine et al., 1997, pp.71–80)

In letter/sound instruction, care should be taken to model the sounds correctly without distortion and to give a great deal of practice with corrective feedback. Students should master each set of letter sounds before being asked to move on, and a distributive review cycle should be used to build retention.

Word Blending. Students should begin to blend words as soon as they have developed awareness of the phonemic structure of words and knowledge of the association of letters to sounds. Students do not need to know all the letter-sounds prior to beginning blending instruction. They will, however, need explicit instruction and repeated opportunities to practice and receive feedback. The core activity in systematic explicit decoding instruction is blending single sounds into words (Moats, 1998). The teaching sequence is as follows:

1. Teacher writes "am" and "fit" on the board.
2. "Watch. When I touch a letter, I'll say the sound. I'll keep saying the sound until I touch the next letter. I won't stop between sounds."
3. Teacher touches under each letter for 1 to 1½ seconds and says sounds without stopping. "My turn to sound out this word. aaammm." (Model)
4. Teacher touches under each letter for 1 to 1½ seconds and says sounds without stopping. "Sound out this word with me. aaammm." (Lead)
5. Teacher touches under each letter for 1 to 1½ seconds. "Your turn. Sound out this word by yourselves." (Group Test)
6. Teacher calls on individuals to sound out words. (Individual Test)
7. Everybody, "What word?" Students say entire word quickly; that is, at a normal rate.

In word blending instruction, use only letter/sounds students have mastered. Begin word blending when students know four to six sounds. Once students can blend simple words, begin using those words in simple connected text. Review letter sounds before each activity, and include examples of all types of words students have learned in review word drills (VC, CVC, CCVC, etc.) (Carnine et al, 1997, pp.82–91).

Reading Connected Text. Do not assume that learners will automatically transfer from reading words correctly in lists to reading words in passages. When introducing passage reading, give students prompts and procedures for transferring word recognition skills to passages. The focus at this point is on accuracy with emerging fluency. Provide initial practice in text with only words students can either sound out or have memorized. Continue repeated opportunities to read words in situations where they can apply their developing phonics skills with high success.

Begin reading words in passages after students can read words in lists at a rate of one word per 3 seconds. At this point the prompts will look like the following:

1. Early prompt: "Figure out the word. Say the sounds in the word to yourself." Give 3, (eventually 2, then 1 to 1½ seconds) to think. Then clap or tap for the group to say the word out loud. This phase usually lasts 1–2 weeks.
2. Later prompt: "Each time I signal (clap or tap), read the words in the story the fast way." (Give about 1 second per word or pace yourself to the middle reader in the group.)
3. Provide repeated opportunities for students to read and reread passages to develop accuracy and fluency.

The Error Correction Procedure is

1. Allow the student to finish the sentence.
2. Have the group or the individual sound out the word.
3. Say the word at a normal rate.
4. Ask the student to return to the beginning of the sentence (Carnine et al., 1997, pp. 91–94).

Irregular Words. Irregular words are those that do not conform to usual conventions of spelling. Irregular words are also those that do conform to conventions of spelling, but have letter/sound correspondences that have not been taught to the students yet. The teaching format for irregular words is the following:

1. Tell the student the word.
2. Ask them, "What word?"

3. Have students spell the word.

4. Ask them what word they spelled.

5. Confirm the word by saying, "Yes _____."

Limit the number of irregular words taught. If students are confused, stop introducing words. Preteach words before they appear in passages and provide cumulative review.

The Error Correction Procedure is

1. "This word is _____." (Model)

2. "What word?" (Test)

3. "Spell ______."

4. "Read the sentence again." (Delayed Test) (Carnine et al. 1997, pp.109–113).

Advanced Word Recognition. In the very early stages of reading that we have been discussing to this point, students attention has to be drawn to individual letters, the sounds those letters make, and the way the sounds combine to make words. As competence in reading increases, students must learn to become automatic in recognizing words. There is considerable evidence that fluency develops as students begin to respond to patterns and process familiar letter sequences as units. This is the orthographic stage in which it is important for students to become aware of patterns of letters in words. A massive amount of exposure to words is required to develop this awareness. Some of the exposure can be through word lists, but a substantial amount should be in reading text that contains vocabulary controlled to provide repetition of familiar word patterns (Adams, 1990b; Ehri, 1991).

By the middle of the first grade we would hope a child has mastered all consonant and short vowel sounds, can blend CVC, CCVC, CVCC, CCVCC words, recognize a good supply of irregular words, and can read end of year first-grade material at approximately 20 words/minute. It is at that point that the child is ready to be introduced to the CVCe pattern. This is the sharp digression from what the child has been taught to this point. No longer does each letter make one predictable sound that can be blended. Now one letter can make two sounds, and one letter's job is not to make any sound at all, but rather to govern the sound another letter makes. It is important that teachers not underestimate the complexity of this change. Students must be given very explicit instruction and lots of guided practice with feedback in order to master this stage.

It is very common to find older remedial readers who are not fluent at this distinction. One can only wonder if the confusion would be as great if the students had received explicit instruction and sufficient practice when they were first introduced to this concept in primary school.

Introductory format for teaching CVCe words:

1. Explain and use examples to show that an "e" at the end of a word makes a vowel say its name.

2. Point to a word (CVC or CVCe) and ask, "Is there an 'e' at the end of this word?"

3. Point to the vowel. "So what do we say for this letter?"

4. "So, what is the word?"

5. Provide short mixed lists of CVC and CVCe words daily, giving lots of opportunity to respond with error corrections.

6. Use CVCe words in passages when students can respond correctly in lists for 2 consecutive days.

Discrimination CVCe format: Use this to see if students understand when to apply the rule.

1. Use similar CVC and CVCe words such as "hop" and "hope." Or "dim" and "dime."

2. Read the list twice. The first time the teacher gives all the prompts in the Introductory Format. The second time the teacher just says, "What word?" Students should master all lists; that is, be able to get all words right the first time.

3. Fluency with CVCe CVC distinctions should be well established by the end of second grade (Carnine et al., 1997, pp. 166–167).

A second advanced word recognition skill students must develop in the orthographic stage is letter combinations in words, such as th, wh, ee, ea, ou, ai, and aw. The goal, again, is for students to see the patterns and respond to them automatically. Effective teaching should be as follows:

1. Teach only one sound (the most common sound) per combination. (See Carnine et al. (1997, p. 162) for a list of most common sounds of letter combinations.)
2. Separate sounds that are auditorily and visually similar (oa, oi, oo).
3. Teach sounds that sound alike together (ai and ay, oy and oi).
4. Use the same formats as beginning letter/sound.
5. Do word drills using the regular word format.
6. In the first part of a word list, underline the word part the student is learning. Ask, "What sound?" "What word?"
7. In the second part of the word list do not underline the letter combination, but still ask, "What sound?" "What word?"
8. Use a carefully designed review cycle so letter sounds that were mastered are not forgotten (Carnine et al.,1997, pp. 161–166).

Advanced word recognition actually entails learning and responding automatically to phonic generalizations about letter patterns. Some educators, therefore, would suggest teaching students to memorize those generalizations. Research, however, suggests that rule memorization is not productive. There are several possible reasons for this. First, generalizations are not reliable and therefore are confusing to students. Second, students do not need to know the rule. Rather, they need to respond to words quickly. Giving the student repeated opportunity to respond to words with feedback can best do this (Adams, 1990b).

Fluency in Reading. The human brain has capacity for only a limited amount of attention. To accomplish high-level tasks, subordinate tasks must be overlearned to the point of automaticity. This means that if letter sound identification is slow, then word blending will be laborious. If word identification is slow and laborious, then it will demand a great deal of attention, and little attention will be left to allocate to the meaning of the text. At each stage of early reading, therefore, students must be encouraged to move from accuracy to fluency before moving on to the next stage (Juel, 1991; Samuels, 1979). Teaching of fluency should proceed as follows:

1. Be sure students are accurate. If students have error rates over 10%, then either move them to easier material for fluency training or delay it until reading is more accurate.
2. Fluency training should begin when students are reading 30–40 words/minute.
3. The role of the teacher is to provide a model of how fluent reading sounds, to structure the learning environment to ensure passages are of appropriate difficulty, and to provide feedback.
4. Begin with highly decodable text and move slowly to less controlled text. Also include words progressively more phonically and structurally advanced.

Continued Points of Debate in Early Reading Instruction

USE OF CONTEXT IN WORD IDENTIFICATION

It was once thought by expert reading researchers that good readers were fluent because they used context to predict words and thus were able to skip over many letters and whole words. It followed then that an important skill to teach poor readers was to guess what word would make sense based on pictures or the surrounding text. A preponderance of research over at least 15 years has shown that this belief and practice is not substantiated (Stanovich, 1994). While good readers actually look at every letter in every word, poor readers are the ones who rely on context clues for word identification. At this point we can only presume that this is because orthographic processing in poor readers is not adequately developed (Adams, 1990b).

There are a number of problems associated with using context clues for word identification. First, it is a form of guessing and therefore unreliable. Second, the less frequent words that a budding reader may need help identifying are content words that often carry the most meaning. The words surrounding those content words are likely to be structure words that offer little meaningful context. Finally, the act of guessing and moving on provides no incentive to study the word and its letter patterns. Thus, the student is no better prepared to identify the word the next time it appears. By getting the word quickly with context clues, the student actually misses out on the practice that would make the student a better reader.

CHOICE OF TEXT FOR BEGINNING READERS

The type of text that early readers should be given for instructional practice is a second point of debate. Some argue that predictable text that follows a pattern in which words can be anticipated or guessed is best. It does not limit the words that can be used, and yet it allows the child to read quickly and builds confidence. Research suggests that this is, in fact, valuable for preschool reading in order to build print awareness (Moats, 1998). Once actual word identification instruction has begun, however, this approach meets with the same objections as the use of context for word identification approach discussed above.

Others argue that words for beginning readers' texts should be chosen for the frequency of the use in the oral language of young children. This method allows for text that sounds natural to the child. Many high-frequency words, however, are irregular. Text reading, then, requires memorization of a large number of words as whole words. This method also makes it difficult for the children to see the connection between the phonics lessons they may be receiving and the text they are asked to read.

Still others in the reading community suggest that beginning readers should be given text with a high percentage of words that the student can identify, a few irregular words that they have memorized, and the phonics principles they have mastered to that point. By using a high percentage of decodable words, of course, limits the words that can be used and leaves decodable text open to the criticism that it is unimaginative and stilted.

Juel and Roper-Schneider (1985) studied 11 first-grade classrooms in one district. All the classrooms used the district's structured phonics lessons. The classrooms were then split. Half practiced reading in text that supported phonics lessons with decodable words based on principles the students had learned. Half read in text with words that were chosen for their high-frequency rather than adherence to phonics principles. By the end of the year the students who read in connected text with decodable words read significantly more words, and could identify more words that had not been directly taught. There is some evidence that the choice of early text might influence skill in reading at least as powerfully as the type of skill instruction. (See Adams (1990b, pp. 272–292) for a more thorough discussion of this topic.)

INTERVENING WHEN STUDENTS ARE NOT MAKING ADEQUATE PROGRESS

The best intervention is a well-designed and well-delivered reading curriculum in the first place. We now have converging research on the importance of reading skill to success in later life, on the critical nature of having reading skills established in the primary grades, on how to teach beginning reading, and on how to monitor each child's progress. To ignore this preponderance of evidence and not put it into practice because of a different set of beliefs or values is indefensible.

Despite this encouraging scenario, however, the battle is not entirely won. Children coming into kindergarten at-risk for reading failure are a fragile lot. Although many respond to good instruction and careful monitoring, there is still a small group of non-responders. The best interventions for those students are similar research-based activities but in smaller groups so students have more opportunities to respond and get feedback. For a discussion of this topic see O'Connor (2000). She concludes that for some of our more difficult students we will need to be prepared to do long-term interventions even as we improve instruction for all students.

Systems Level Issues in Beginning Reading

ADOPTING BEGINNING READING CURRICULUM

By now it is apparent that very systematic and explicit instruction in letters, spelling patterns, and words are critical if students are to move from being non-readers to being readers in the primary grades. It is imperative that educators not underestimate the complexity of the task. It is unreasonable to expect that simply teaching teachers about the elements of good reading instruction will result in children being well instructed. They cannot be expected to create their own materials. Therefore the adoption of a beginning reading curriculum that follows research-based reading principles is important. Adoption committees must look to see that phonics instruction is explicit rather that implicit, that use of context is not encouraged as a significant method of word identification, and that decodable text is presented that develops in the same sequence as the student's phonics skills. They should also determine if large-scale research has reported positive results for the curriculum. Three curricula that have documented student achievement through large-scale research include Direct Instruction (Reading Mastery), Success For All, and Open Court. The National Center for the Tools of Educators (NCITE) also has developed a *Consumer's Guide to Evaluating a Core Reading Program Grades K-3*. It can be obtained from their website at http://idea.uoregon.edu/~ncite/.

SERVICE DELIVERY

It is common for an educational team to design a best practice instructional plan for a child or school, but not implement the plan because of service delivery difficulties. Careful problem solving will be needed to surmount these barriers. What follows are service variables that can be altered for intervention purposes:

Grouping. It often may be necessary for students to be placed in homogenous groups based on skill-achievement level for at least a portion of their reading instructional time. Grouping allows for explicit instruction, in which skills are neither too difficult nor too easy and in which students get multiple opportunities to respond with feedback. Providing skill groups for students and keeping them flexible based on data that reflect student progress is a staffing and scheduling challenge to schools. Frequent skill measurement will make it clear when children need to move to different skill groups. School psychologists will need to provide problem-solving assistance to grade level teams as they learn to use data to group students.

Time for Team Review of Data and for Problem Solving. Grade-level teams should have time scheduled to meet regularly to make change decisions. Even schools that agree philosophically with grouping and scheduling for data review will have be creative to find the time to allow it to happen.

Extra Time for Instruction. A major way in which children differ in learning to read is in the number of repetitions they need to master skills. A school that meets the needs of all students will have a plan in place so children can get extra time on the critical skill of reading. This may mean having the child skip less critical instructional areas. It may also mean allowing staff time away from other duties.

STAFF DEVELOPMENT

Fulfilling the promise of teaching all but a small percentage of students to read well (Lyon, 1998) will require that teachers and administrators in our schools know and understand the complexity of teaching children about the structure of language. This would require knowledge in how children actually learn to read the words on a page. Unfortunately in many teacher education programs even the faculty needs much more grounding in the science and pedagogy of reading. School psychologists need to be aware that almost all teachers of beginning reading, classroom teachers and specialists, will have gaps in their knowledge base. In-service training efforts are needed to provide teachers the basics of research-based reading assessment and instruction. See Moats (1997) for a thorough discussion of this topic.

ADVOCACY

There is a convergence of research evidence around the development of early literacy skills. At this point, we know what skills are predictive of reading risk and we know how to reliably and validly assess these skills. Given that the data are overwhelming in terms of the types of instructional strategies young students need to be successful readers, it is disconcerting that the major curricula available in our schools do not provide kindergarten and first-grade teachers with the materials they need to teach early literacy skills. While most mainstream curricula have some lessons that focus on phonemic awareness, they rarely are explicit enough or emphasized enough to provide the kind of practice at-risk students need. Thus, to provide adequate support for these at-risk students, many of the interventions have to be added on.

There is a clear role for school psychologists in advocating for instructional changes for kindergarten and first-grade students who need more explicit instruction. This advocacy can occur at the building, district, and state levels. At the individual building level, school psychologists can generate interest around this topic by providing continuing professional development on the current knowledge base for early literacy. As an outcome of training efforts, school psychologists might recruit interested teachers in gathering and developing curriculum materials that address student needs and organize discussions about how instruction can be delivered to students in need. Further, school psychologists are the most likely candidates to organize school-wide assessments for kindergarten and first-grade students that would identify students for targeted early literacy intervention.

At the district level, school psychologists could play a number of important roles. As a member of a district curriculum adoption committee, a school psychologist could advocate that curricula be chosen based on empirical evidence for strong achievement outcomes and the inclusion of explicit instruction in letter sounds and sound blending. Curriculum adoption can be a highly political undertaking, and a voice for empiricism should be represented. A further role is to advocate for district-wide assessment of early literacy skills for entering kindergarten and first-grade students. Of course, assessment without plans for remediation of identified deficits is of no use to anyone.

Finally, there also may be a role for school psychologists at the state level. Advocacy can be focused either at the legislative or bureaucratic levels. A number of states have undertaken reading initiatives that have provided best practices guidelines. The National Center to Improve the Tools of Educators at the University of Oregon has developed a Policy Options handbook for developing a reading initiative (Carnine, undated). This is a great resource for gathering ideas about how a few other states have implemented state-wide reading initiatives. The main message must be this: There is a strong empirical base for the early identification of children at-risk for reading failure; there is a strong empirical base for targeted instruction in early literacy skills to change this trajectory and reduce reading failure; and without such identification and intervention, large numbers of students will continue to fail high stakes state testing resulting in students ill prepared for life in the twenty-first century.

SUMMARY

The last decade of research has strengthened the empirical foundation for the development of early literacy skills such that there is irrefutable evidence for how reading failure develops and methods for preventing it. In their recent report, the National Reading Panel (2000) came to some important conclusions about what is known based on solid research evidence:

1. Teaching children to manipulate phonemes in words was highly effective under a variety of teaching conditions with a variety of learners across a range of grade and age levels and that teaching phonemic awareness to children significantly improves their reading more than instruction that lacks any attention to phonemic awareness (p.7).

2. Systematic phonics instruction produces significant benefits for students in kindergarten through sixth grade and for children having difficulty learning to read (p. 9).

3. Guided repeated oral reading procedures that include guidance from teachers, peers, or parents had a significant and positive impact on word recognition, fluency, and comprehension (p. 12). Conversely, the panel did not find a positive relationship between independent reading and reading achievement.

Given this information, school psychologists need to advocate for appropriate curricular and instructional interventions for kindergarten and first-grade students and in preschools when the opportunity presents itself. This instruction should focus on direct and explicit instruction in phonological awareness, letter sounds and blending, vocabulary development, and fluency practice. Further, school psychologists can be instrumental in implementing school wide assessments of young students in early literacy skills, which are predictive of reading failure. These assessments can help identify those who will benefit the most from early intervention and prevention of reading failure. An additional role is to identify teacher training needs for delivering a quality reading program, and to arrange for training and opportunities for teachers to plan and collaborate with one another. Finally, school psychologists can increase their knowledge of specific interventions for at-risk readers in order to become better consultants to early grade teachers. In many ways, preventing reading failure is perhaps the best role of all for school psychologists!

Best Practices in Developing Local Norms for Academic Problem Solving

Lisa Habedank Stewart
Minnesota State University Moorhead
Ruth Kaminski
University of Oregon

OVERVIEW

We compare ourselves to others and compare our students to their classmates everyday. Teachers typically are able to "rank order" their students and determine who has the highest academic skills, who has the lowest, and who is in the middle. As school psychologists we use tests and test norms to operationalize and objectify student comparisons. Norms provide a standard of achievement or performance of a particular group on a given task or test and are often used as the standard of comparison for a student. An individual student's performance may be compared to a broad group of students or to a particular subgroup (i.e., students whose first language is not English) at a national, regional, or local level.

This chapter addresses the development of local norms; that is, norms that represent students from a particular educational system. Specifically, this chapter focuses on developing *academic* local norms for educational problem solving. Another chapter in this volume focuses on developing behavioral local norms. Local norms provide a standard for a student's performance compared to others in the student's own education cooperative, district, building, or even classroom. One of the advantages of local norms is the potential for a very specific and relevant comparison to other local students who share similarities in educational and other background variables. Local norms also present the opportunity to compare student skills against local goals or predetermined "benchmarks" and link normative data collection with other types of educational decisions. For the school psychologist, involvement in developing local norms provides a unique opportunity for leadership at the school or school district level while creating a database that has utility for everyday consultation and decision making.

The use of norms in the schools is not a new phenomenon. Since the early 1900s normative comparisons have been used extensively in the schools to describe individual differences (Bergan, 1985). These comparisons, typically involving published achievement and intelligence tests, have been used widely as part of the special education screening and eligibility process. The concept of local norms, likewise, is not new. Many psychological measurement texts describe local norms as norms developed by the test users themselves to represent a narrowly defined population. Some of the references to local norms in the literature describe norms developed on nationally normed, published tests in order to represent a specific population. For example, Tempest (1998) developed norms for the WISC-III on Navajo schoolchildren in a New Mexico county for the purpose of having a local Native American comparison as well as a national comparison.

Since the 1970s, an increasing number of school districts have created local norms to more directly represent the local population and local school district's academic goals and outcomes, rather than the performance of particular subgroups of students on items on a published test. For example, local norms have been developed using Curriculum-Based Measures (CBM) of student academic performance (Marston & Magnusson, 1988; Shinn, 1988). The normative data collected on these CBM tasks are used to describe the expectations for a student's basic academic skill performance in general education. Typically the norms are collected three times per year (fall, winter, and spring) using a sample of students from the local school building or district who complete CBM tasks tied to the general education curriculum. These norms can be used for several years as a comparison for students referred for screening, eligibility, or goal-setting decisions, with "renorming" taking place every 5–7 years (or more frequently as necessary if the student population demographics change) to keep the norms current.

As school districts have experimented with creating and using local norms, the types of tasks that are normed have broadened to include pre-literacy skills called Dynamic Indicators of Basic Early Literacy Skills (DIBELS; Kaminski & Good, 1998) or the use of literature-based CBM reading probes (Hartman & Fuller, 1997). Additional uses of the local norming process and data also have evolved, such as collecting local norms on all students every year in a way that becomes incorporated into the school's normal operating procedures (Kaminski & Good, 1998; Shinn, 1998). In addition to providing a normative database for making decisions about referred students, having a regularly updated database on all students could be used (a) for reporting individual or group scores to teachers, parents or other agencies, (b) as a proactive screening tool to identify students who are not keeping up with peers or to some preset standard, or (c) to detect academic or behavioral trends over time. Although many of these expanded purposes are not norm referenced decisions, the steps for collecting the data are similar and often include developing local norms. This chapter will focus on the steps for developing local norms, but also will provide examples of expanded uses of that data collection process.

STRENGTHS OF LOCAL NORMS

Although developing norms does involve time and resources, the strengths of local norms can make this a wise investment. For most educational decision making, local norms are representative of a meaningful comparison group on tasks relevant to the problems at hand. Specifically, local norms may decrease the likelihood of bias and increase teaching/testing overlap and norm utility across educational decisions.

Decreasing the Likelihood of Bias in Decision Making

Local norms can decrease the likelihood of bias in decision making because they represent a meaningful comparison group. Local norms represent how a student performs in relation to others from his or her grade and school, a comparison likely to be representative of the age, grade, race, educational background, and geographic and socioeconomic factors relevant for educating this student (Shinn, 1988). Gerber and Semmel (1984) argue that general education teachers already use their own "local norms," where a student's performance falls in relation to the other students in the class, to determine who gets referred for more intensive services. Local norms make this comparison part of systematic and data-based decision making.

Local norms also can decrease the likelihood of bias in decision making because they promote the identification of educational needs and a problem-solving orientation. When education professionals base decisions on agreed upon, important educational outcomes operationalized in the form of locally normed educational tasks, they can identify and help students who perform significantly below their peers and thus are at risk for failure in the schools and in society (Shinn, Collins, & Gallagher, 1998). Although using local norms will not guarantee non-biased assessment or decision making, the process of creating and using local norms may help local schools and communities clearly communicate what is expected of students, identify current patterns of student performance, and make more objective and accountable the process of identifying students for special services or determining standards for student progress. Because local norms provide a snapshot of student performance on important educational targets across classrooms within a school and/or schools within a school district, local norms can even be used to demonstrate whether patterns of local performance are changing over time.

Opportunity for Greater Teaching/Testing Overlap

One of the complaints about the use of nationally normed, published tests is the lack of teaching/testing overlap. Several studies have documented that differing levels of test-content overlap with the curriculum affects student scores (e.g., Good & Salvia, 1988; Shapiro & Derr, 1987). Local norms give the school system flexibility for developing comparison data on educational outcomes and tasks that students have been exposed to in the school curriculum. Instead of making decisions based on questions that may or may not reflect content taught as part of the school's curriculum—and often assessed using bubble sheets or requiring a small number of responses—schools can base decisions about students on tasks related to curricular content. This flexibility means that the norm comparison data are directly relevant for making decisions about a student's performance compared to local expectations.

Utility Across Educational Decisions

Normative comparisons typically are used in educational decision making only to identify and describe the severity of a problem (e.g., for screening or eligibility decisions). A strength of local norms is increased utility across educational decisions. What national norm comparisons often lack is (a) the ability to consider the student's immediate environment in defining problems and (b) a tie between the information used to define the problem and other decisions in the public school system. Local norms operationalize the expectations for a student's immediate educational surroundings and can be useful across the range of educational decisions. They can be used to compare a referred student to his local peers for screening or eligibility decisions—perhaps in conjunction with national norm comparisons. However, local norms also can be used to identify students at risk for school failure, as a guide for setting educational goals, and even to help determine if a student is ready to exit special services.

A related strength of local norms is that all local educators can use the same general education outcomes "ruler" or decision-making framework for many types of educational programs such as Chapter I, English as a Second Language (ESL), Talented and Gifted (TAG), general education, and special education. Normative comparisons are already used to identify students for many types of educational programs. However, the tests used between and within these programs may differ, making it difficult to compare the achievement of one group of students (e.g., students served in Chapter I programs) to another (e.g., student identified as learning disabled with an Individualized Education Plan (IEP)). Local norms can provide a consistent general education outcomes ruler that allows for a variety of comparisons between and within all of an educational system's programs. Because school psychologists often see how decisions get made across a variety of programs, they are in a unique position to highlight the utility of local norms across programs.

LIMITATIONS OF LOCAL NORMS

Despite the strengths of local norms, several areas of caution must be kept in mind when developing local norms. It is important the local norms are not misinterpreted. It also is crucial that people developing and using local norms understand that although the local norms will reflect the performance of local students, "typical" performance for that district or building or classroom is not necessarily acceptable or ideal. School psychologists are in a unique position to model appropriate local norm use and interpretation and address any misconceptions regarding local norm data.

Misinterpretation

Because not all educators are familiar with the use of local norms, it is important to define both the sample and the measurement tasks. Parents, teachers, and others should be informed about who is represented in the normative sample, what the students were asked to do, and how the scores were derived. It would be important for accurate interpretation, for example, to know that a student's CBM reading performance was measured on reading passages from the general education curriculum at his or her grade level and compared to others at the same grade level in the school district.

Using local norms with a small number of cases in the norm sample (e.g., fewer than 100 students per grade) can be problematic. If the sample size is small, then the norm may be unstable and should not be used as the most important normative comparison for making eligibility decisions. Also, with a small sample size, infrequent elements in a population may not be represented. Small or limited sample size is not necessarily a problem, however, as long as the norm is interpreted appropriately. For example, if a classroom norm is used to help define what is expected of the student in that classroom, then a statement should be made about the possibility that expectations of student performance in another classroom may differ. This does not mean the classroom comparison is not meaningful; it may be quite useful in understanding the difficulty a teacher is having in accommodating a student's needs.

Local Norms and Defining Acceptable Performance and Curricula

Shinn (1988), in his description of developing CBM local norms for use in special education decision making, expressed concern that local normative performance would be seen as the goal for all students. Using a local norm to describe general education expectations does not mean that local normative performance is necessarily acceptable. For example, if a student's spring oral reading fluency is within the range of his third-grade peers—but his peers are reading a median of 20 words correctly per minute in typical grade-level material—the conclusion would be that the student is not different from peers. However, a reading level of 20 words per minute in third grade in typical grade-level material would not be an acceptable level of reading achievement for all third grade students. Rather than relying solely on local norms, empirically derived benchmark reading rates may be used as a criterion in conjunction with local norms to determine if a student's performance is acceptable. For example, Good and colleagues (Good, Simmons, & Kame'enui, 2001) have examined the utility of student performance on CBM reading in predicting reading success or failure on grade 3 high-stakes reading achievement tests and found that students who read grade-level material at a rate of 110 words correct per minute or better were likely to meet or exceed expectations on the Oregon Statewide Assessment. Students who were able to read fewer than 70 words correct per minute on grade-level material were not likely to meet expectations on the Oregon Statewide Assessment.

In addition to empirically derived benchmark criteria on local norm tasks, regionally or nationally normed general achievement tests may be used periodically to assess the skills of the local school population and provide data about how the school population as a whole compares to regional or national standards.

Another concern is that developing local norms will somehow advocate the use of a particular published curriculum. Local norms tasks should reflect important educational outcomes. The norming materials themselves may or may not be derived directly from the school's adopted published curricula. Having local norms drawn from published curricular materials does not mean that the adopted curriculum is the most effective, only that students are expected to learn from the adopted materials. Local norms will provide data on student's level of performance and rate of growth in the curricula.

BEST PRACTICES

Best practices in developing local norms for problem solving is based on how the norms will be used for educational decision making. The purpose(s) of norming for different educational decisions will influence the task of selecting important and valid behaviors to norm which, in turn, influence the following procedural steps of norm development: (a) selecting a level of norm, (b) creating a measurement net, (c) implementing a sampling plan, (d) collecting the data, and (e) organizing the data for use. Examples of the use of local norms for making decisions, the selection of important and valid behaviors to norm, and, finally, the step-by-step procedures of norm development will be presented in the following sections.

Uses of Local Norms for Decision Making in a Problem-Solving School System

Knowing how to use the local norm data requires an understanding of the problem solving steps and their relation to local norms. Deno (1988) proposed that educating tough-to-teach students is a problem-solving process. He outlined five problem-solving steps, or decisions, that correspond to the administrative steps of most special programs: (a) problem identification, (b) problem certification, (c) exploring solutions, (d) evaluating solutions, and (e) problem solution. In light of the recent emphasis on the importance of early intervention, however, another aspect of solving problems could be added to Deno's five-step process. Prior to the first step of problem solving could come problem prevention. Possible uses of local norms in each of these problem solving decisions, including prevention, will be outlined.

PREVENTION

Prevention efforts can be focused on all students or a subset of students who are at-risk for developing future problems. By using the norming process, data could be gathered on each student to determine if they are at-risk for later educational problems. This provides both a normative database and a way to screen and monitor students. With the emphasis on standards and accountability in many areas of the country, some districts have identified benchmark scores on the norming tasks based on research standards or analysis of their own norm data over time. Instead of waiting until a student is referred for special education, all students who are below these "benchmarks" based on their norming scores are monitored more closely, with additional services provided as needed. School psychologists could introduce or provide support for the use of local norms in this proactive, prevention-focused way.

One application of use of local norms form prevention based on benchmarks is systematic screening of all students at regular intervals using DIBELS. DIBELS include a series of pre-literacy tasks that build on each other and predict later reading success. By using the same time frame (e.g., fall, winter, spring) and basic steps as the development of local norms for older students, all kindergarten and first grade students could be tested on their development of these pre-skills (Kaminski & Good, 1998). For example, DIBELS data could be used to identify kindergarten students who are low in phonological skills. Those students could be monitored more closely and provided with instruction specific to their needs, perhaps changing the students' trajectories and preventing future referrals. In essence, using DIBELS local norms in prevention efforts takes problem solving to an earlier stage of skill development, aiding in the identification and treatment of pre-skill problems to prevent basic skill problems down the road.

PROBLEM IDENTIFICATION AND CERTIFICATION

Like national norms, local norms may assist in problem identification for a student referred to a school team for pre-referral interventions or problem certification for a student undergoing assessment for special education eligibility. Local norms can be used to define what is expected of a student. For example, comparing a student's score to a local oral reading norm can determine if the student's reading score falls within the average range of other students in that district, building, or classroom. That average range represents what the teachers see as typical reading performance in the classroom. If the student's reading falls below that average range, then educational personnel may conclude that the student's performance does not meet expectations and therefore a problem exists that warrants a pre-referral intervention(s) and further assessment. If, upon further assessment, the student's reading scores continue to fall far below typical student performance, then the conclusion that the problem is important and warrants intensive school services (e.g., special education) is supported.

EXPLORING AND EVALUATING SOLUTIONS

Local norms can be useful at several other levels of a school's problem-solving framework. Once the problem has been validated, goals are set and services are provided to meet the student's needs. Local norms can be used to help set goals. IEP and Chapter I goals, for example, can be based on the typical performance of students in the local norm sample. Tying student goals to typical general education performance reminds teachers to strive for student success in the general education curriculum. Once goals are set, the student's individual progress is monitored at regular intervals and the trend line is compared to his or her goal to determine if services are effective. Services are modified if goals are not being met. Although local norms cannot be used for frequent individual progress monitoring, they can provide guidance in goal setting and encourage the use of data-based decision making.

Local norms also can be used to clarify placement in, and organization of, the variety of special services available in the school. By obtaining a picture of the local student population's range of skills (the local norm) and knowing which sections of that population are served by the resources available (e.g., where students in Chapter I, ESL, special education, TAG, and at-risk programs perform on the norming tasks), decisions about services for individual students and the organization of programs can be more data based.

PROBLEM SOLUTION

Finally, local norms can be used in determining when a student can be exited from a program or moved to a less restrictive environment (i.e., problem solution or reintegration). Student performance within the range of typical general education students suggests consideration of exit from the special program. Relatedly, student performance within the range of the lowest achieving general education students in the classroom, school, or district sample could be used to determine when a student could be reintegrated into a less restrictive setting (Powell-Smith & Stewart, 1998; Shinn, Habedank, Rodden-Nord, & Knutson, 1993).

EXPANDED USES OF THE NORMING PROCESS

Other uses of the norming data collection process have evolved over time. The addition of prevention is one such evolution that promotes problem solving at an earlier point in time. Other expanded uses include the use of local norms for accountability and communication purposes or program evaluation. Individual, classroom, building, or district reports can be generated from local norm data. Local norm data can be used in report cards to show where the individual student stands compared to the majority of his or her peers on the norm tasks. Local norms allow a school or district to generate their own summaries, graphs, and tables that can be individualized for local purposes.

Local norms collected across years also can be used to evaluate program/curriculum effects, given fairly stable student populations and demographics. Likewise, local norms collected across years could be used to evaluate the effects of population or demographic shifts, given fairly stable service delivery systems and program/curriculum. Local norms collected for the purpose of program evaluation or other administrative purposes may require a higher level of expertise and a more standard set of tasks and measurement materials than local norms developed for student-centered decision making (Tindal, 1988; Tindal & Marston, 1990).

Selecting Important and Valid Behaviors to Norm

Once the intended uses of the local norms are clear, the next step is deciding what behaviors or educational tasks will be normed. Examples of local norms in the recent school psychology literature and in this chapter have been associated with CBM or DIBELS. Developing local norms using behaviors important in the general education environment could include other areas of assessment and norming tasks. For example, local norms could be developed on social behaviors (Canter, 1995), physical education skills, or secondary content areas such as social studies or science (Espin & Tindal, 1998). What is most important in making decisions about what to norm is that the data are relevant and valid for decision making.

CHOOSING RELEVANT AND VALID AREAS OF ASSESSMENT

To be relevant, local norm data must be related to important educational outcomes for students. Local norms in basic academic skill areas are a logical place to begin because these areas generally have been the most "important," well-defined, and accepted educational outcomes in our schools. The DIBELS tasks and the use of the norming process for prevention efforts also are tied to important general education outcomes, although the tasks may be predictors of that outcome (e.g., phonological skills and understanding letter/sound correspondence are predictive of reading) and reflect the fact that the expectations for students at the pre-literacy level involve a broad foundation of pre-skills needed for future academic success.

To be valid, local norm data must be reliable and accurate, have relatively normal distributions, and be sensitive to educational change. To increase the likelihood that a local norm has these qualities, tasks that are normed must have standardized administrations and scoring procedures, with proven test-retest reliability and content validity. To be useful in decision making, the norms must reliably differentiate students' levels of skill on the task (e.g., performance on the tasks needs to be relatively normally distributed). The further a distribution is from being normal, the more difficult it becomes to use the norm to set goals or determine if a student being assessed is different from peers. The tasks being normed also must provide enough opportunities for responses to show an increase when that skill is taught in the classroom.

The Use of CBM Tasks. It is a challenge to find measurement tasks that (a) fulfill the validity requirements, (b) are time-efficient and affordable, and (c) provide data tied to important general education expectations. This challenge is one reason that local norming in the basic skill areas developed in conjunction with CBM. CBM tasks have a database documenting their reliability, validity, sensitivity (Good & Jefferson, 1998; Marston, 1989), and relatively normal distributions in local norm data collection (Magnusson, 1986; Tindal, Germann, & Deno, 1983). Furthermore, CBM is not just a technology, but a measurement system designed for use in a problem-solving system. Using local norms to operationalize the expectations of the general education environment is one of the defining characteristics of CBM (Deno, 1985, 1986).

The Use of DIBELS Tasks. Based on the format and use of CBM in the areas of basic skills, DIBELS have been developed to assess the acquisition of early literacy skills prior to formal reading instruction and the development of reading skills. DIBELS have been designed to measure the "big ideas" of early literacy, that is, those early literacy skills that are supported by research as being highly predictive of and causally related to reading success—phonological awareness, understanding of the alphabetic principle, and accuracy and fluency in reading connected text. These early literacy skills are hierarchical in nature. Thus, achievement of phonological awareness skills in kindergarten is related to the acquisition of the alphabetic principle in the beginning to middle of first grade and to reading achievement at the end of first grade. Ongoing research on DIBELS documents the reliability, validity, and sensitivity of the measures (Early Childhood Research Institute, 1998, 1999; Kaminski & Good, 1996,1998). DIBELS are used by comparing the performance of an individual child or groups of children at the classroom, building, or district level to empirically derived "benchmark" goals at prescribed times in kindergarten and first grade. Achievement of benchmark goals on DIBELS has been found to increase the likelihood of becoming an established reader by the end of first grade.

Steps in Developing Local Norms

Once decisions have been made about what behaviors will be normed, a series of steps can be followed to develop the norms themselves. Those steps include (a) selecting a level of norm, (b) creating a measurement net, (c) implementing a sampling plan, (d) collecting the data, and (e) organizing the data for use (Shinn, 1998). The steps involved in developing local norms follow a logical sequence. Selecting a level of norm provides an opportunity for reviewing the purposes for developing the norm and the unique characteristics and needs of the local school(s). The completed measurement net is a blueprint for developing norming materials and forces the norm developers to closely examine the local curriculum content, instructional focus, and goals and expectations. The sampling plan identifies the students who will make up the norm sample and allows for logistical planning such as scheduling and final materials preparation. Normative performance data are finally obtained by collecting and organizing the data for use. Each of these five steps is an opportunity for school psychologists to play a leadership or collaborative role in norm development.

SELECT A LEVEL OF NORM

The three basic levels of local norms are classroom, school-building, and school-district norms. In each level the entire sample of students could be used, or a sampling plan could be used to test only a representative portion of students. Classroom and building norms are developed by testing students from an individual classroom or building, respectively. School-district norms can be developed in two ways: (a) selecting a sample of students in each grade from the entire school district population or (b) developing norms in each building and then aggregating all the building norms. The former is generally less expensive, but aggregated district norms provide the benefit of having both building and district norms available. Each level of norm has its own characteristics.

Classroom, Building, and District Norm Characteristics. Classroom norms are a simple way to get started and provide the most direct measure of what is expected of a student in his or her own classroom. However, with such a small norm sample, estimates of the variability within the classroom are problematic and stable percentile ranks cannot be developed. Classroom norms can be used in the referral or IEP process to identify problems and prioritize student needs. They are useful for setting goals for a student or group of students. For example, the goal for low readers in a class could be to perform within the typical range on spring reading norms by the end of the year. Classroom norms also have been used in determining when a student may be transitioned to a less restrictive environment, for example, from a resource room setting to the general education classroom (Shinn et al., 1993).

District norms, on the other hand, provide a more consistent estimate of the performance level and variability of the students within the district. The disadvantages of district norms are that they are a less precise measure of the least restrictive environment for a particular student (e.g., that student's classroom). District norms, like classroom norms, can be used to identify problems, set goals, and prioritize needs. If the district norm sample is 100 per grade or larger, then the norms are stable enough to be used in problem certification decisions as well. Aggregated district norms also could be used to compare the performance of students in different schools for resource allocation and system-wide programmatic purposes.

Building norm characteristics lie somewhere in between classroom and district norms. They are a more precise estimate of the least restrictive environment than district norms and provide a more stable estimate of performance than classroom norms. Building norms can be used for the same general purpose as district norms, including problem certification if the student sample has at least 100 students per grade.

Factors in Level of Norm Decisions. Important factors when selecting a level of norm are the (a) decisions for which the data will be used, (b) amount of curriculum chaos in the district, (c) political and economic structure of the area, (d) characteristics of the local population, and (e) economic and other resources available (Shinn, 1998). As alluded to in the characteristics of different levels of norms, these five factors must be considered and balanced in order to determine which level of norm is both meaningful and feasible.

The development of norms and the level of norm desired depend on the decisions being made. If the school wants to use the data for prevention, the level of norm will be determined in part by the scope of the prevention efforts. For example, one teacher can decide to use DIBELS to monitor pre-literacy development in his or her classroom or the entire district could be involved. If the school wants to use the data for problem identification, problem solution decisions, or goal-setting as part of evaluating solutions, then any level of norm may be appropriate, but the sample size needs to be kept in mind so that student comparisons are accurately represented. For example a classroom norm can be very useful for understanding a referral to the Teacher Assistance Team or making a decision about whether to reintegrate a student, but variations from classroom to classroom should be taken into consideration before interpreting results too broadly. For problem certification decisions it is often necessary to look at stable student samples, which typically requires district norms but may be possible with building norms if the building is quite large.

In some cases, the size of the district, and therefore the norm sample, may be too small for making stable interpretations. In small districts, it may be necessary to collect data across several years within the same district to get a population base of 100 students for a stable sample. Alternatively, two or more small districts with similar demographics may choose to collaborate on a norming project and merge data to achieve a sufficient population base for stable norms.

The other four factors in making a level of norm decision are also important. If the school district has a relatively homogeneous school population and curricular expectations, then district norms are appropriate. When the district is characterized by heterogeneous schools, such as schools that differ in terms of student's language, cultural, and/or socioeconomic backgrounds, district-only norms may not provide the most meaningful representation of student expectations. If the curricular grade-level educational goals or scope and sequence of instruction across a district are inconsistent, then district-only norms may not be appropriate. Schools that have different structures, get funded differently, or have a history of functioning independently from the district "norm" would warrant the development of building norms. If the funds or personnel are unavailable for district norming, then building norms may be more feasible. If resources for building norms are unavailable, then norms can be developed one classroom at a time.

CREATE A MEASUREMENT NET

The second step in developing local norms is creating a measurement net. A measurement net is a grid of the grade levels and representative materials used in norming. The materials should represent the domain of the school year curriculum and expectations for typical general education students. For example, if local norms are desired for mathematic computation at Snowshoe Elementary School, a measurement net could be developed that detailed the grade levels where a math norm comparison would be useful in decision making. At each of these grade levels, the mathematic operations and problem types that best represent student expectations at that grade can be determined and grade-level math probes developed. In the case of academic pre-skills, such as DIBELS, the measurement net would include the pre-skills students would be expected to master over the course of the year in order to be successful in the future. When completed, the measurement net provides a guide for the student stimulus materials that must be developed or obtained. A CBM and DIBELS local norm measurement net for pre-literacy and the four basic skill areas is presented in Figure 1.

It is important that the measurement net truly represent typical material and expectations in each area and grade, not end-of-the-year goals nor already mastered pre-skills. Not every skill or level of difficulty can be represented in the norm materials. Many people and resources may be used to operationally define "typical." District curriculum specialists, adopted curriculum scope and sequence charts, and teachers provide the resources for answering questions such as: *What skills and materials are most representative of each grade's goals and objectives?* or *What materials are the majority of the students placed in for most of the school year?* The actual norming materials can be drawn directly from the adopted published curricular materials identified as typical or can be generic materials created to reflect typical materials and expectations at each grade level.

Figure 1. Sample of DIBELS and CBM local norms measurement net: grades K–6

Grade	*Early literacy*	*Reading*	*Math*	*Written expression*
K	• Onset recognition (fall, winter) • Letter-naming (fall, winter, spring) • Phonemic segmentation (winter, spring)	—	—	—
1	• Letter-naming (fall) • Phonemic segmentation (fall, winter) • Nonsense word fluency (fall, winter, spring)	Scribner Level 1 (winter, spring)	Basic facts (+, -) Mixed probe (+, -)	—
2	—	Scribner Level 2 Common word list	Basic facts (+, -) Mixed probe (+, -)	Age appropriate story starters
3	—	Scribner Level 3 Common word list	Basic facts (+, -) Mixed probe (+, -, x)	Age appropriate story starters
4	—	Scribner Level 4 Common word list	Basic facts (x, /) Mixed probe (+, -, x, /)	Age appropriate story starters
5	—	Scribner Level 5 Common word list	Basic facts (x, /) Mixed probe (+, -, x, /)	Age appropriate story starters
6	—	Scribner Level 6 Common word list	Basic facts (x, /) Mixed probe (+, -, x, /)	Age appropriate story starters

Some hints for creating a measurement net will help avoid problems later. Field test materials and avoid material that is too easy (no variance) or too difficult (nothing to measure). Measurement nets should differ according to differences in the curriculum, purpose for norming and level of norming.

IMPLEMENT A SAMPLING PLAN

One of the strengths of local norms is that the data represent a meaningful comparison population: the students in the same school, curricula, age, grade, and geographical area as the student being compared. A local norm does not necessarily mean norming the entire population, however. It is usually much more efficient to sample from the local population. A sampling plan must be developed that balances the resources available, representativeness of the sample, and information desired. Keep in mind that if the information desired includes information on every student, then sampling is not an option! If the norming process is used for child find and prevention or for individual student reporting, then the school must have the resources and commitment necessary to collect norms on an ongoing basis and on all students. However, if the norming process is used for the sole purpose of collecting a normative comparison, sampling may be used. Options for sampling plans will be described below.

For classroom norms, a minimum of 7–10 students is necessary. Three methods of sampling students for classroom norms have been used: (a) creating a random subset of 7–10 students chosen from the entire class, (b) creating a subset of 7–10 students randomly selected from a pool of "typical" students identified by the teacher, and (c) a combination of testing all the students in the class for group administered tasks and selecting a subset of 7–10 students for more time-consuming individually administered tasks (e.g., oral reading). Choosing every *n*th name in the list from an alphabetized roster of student names or having a computer generated random selection of students are the most typical ways to obtain a random sample of students.

At the building level, 15–20% of the students at each grade level, with a minimum of 20 students per grade, should be randomly sampled (Tindal et al., 1983). If building-level percentile ranks are desired, then a sample of 100 students per grade is needed. Aggregated district norms can be developed by combining building norms if standard measurement materials have been used. If district-only norms are developed, then a random sample of 100 students per grade is needed (aggregating across years if necessary to get 100 students).

COLLECT THE DATA

Data collection begins once the foundation has been laid for collecting well-developed norms. Successful data collection hinges on the development of student testing materials, training data collectors, and scheduling when and where data collection will take place. Student materials need to be prepared that are clear and time-efficient, for example, in booklet form with a place to summarize the data on the cover. Data collectors must be recruited and trained. Getting people involved in the data collection can be a good way of making the data meaningful for them. Parent volunteers, teachers, aides, school psychologists, principals, and school board members can be data collectors. Training materials should be developed so data collectors leave training reliable and efficient in performing the norming administration and scoring procedures. Standardized administration and scoring, clear scheduling and materials, and monitoring integrity of data collection through spot checks or checklists also are key aspects in the collection of reliable norms.

The dates and logistics for norming must be scheduled as far in advance as possible to avoid conflicts with other scheduled school activities. To get a picture of student performance throughout the year, trimester norming (e.g., fall, winter, spring) is recommended, using equivalent but not identical norming materials each time (Shinn, 1988). Of course, classroom norms can be collected almost spontaneously if a classroom comparison is relevant to a decision being made and the materials and trained personnel are available. Norming can take place either within individual classrooms or at a central location in the school(s) such as a cafeteria or media center.

ORGANIZE THE DATA FOR USE

Because there are many potential uses for local norms and different consumers of norming information, the norm data need to be organized so they are easily and accurately interpreted. The data can be summarized at four different levels: (a) individual student raw scores; (b) classroom ranges of scores, medians, and rank orderings; (c) building-level ranges of scores, medians, rank orderings, and perhaps percentile ranks; and (d) school-district-level ranges of scores, percentile ranks, descriptive statistics, within-grade frequency distributions, and across-grade comparisons.

Pictures communicate more clearly than tables and lists, so graphs representing the data are highly desirable. An example of a tabular display of local norm data is presented in Figure 2.

Figure 2 presents a classroom norm rank order of the students by raw score and also gives the classroom range and median. Students in general education, Chapter I, and special education in reading are separated so that comparisons of the achievement levels of students in these programs can be made. Additional descriptive statistics such as group averages and standard deviations could be added to the table for building and district norms. Histograms or fre-

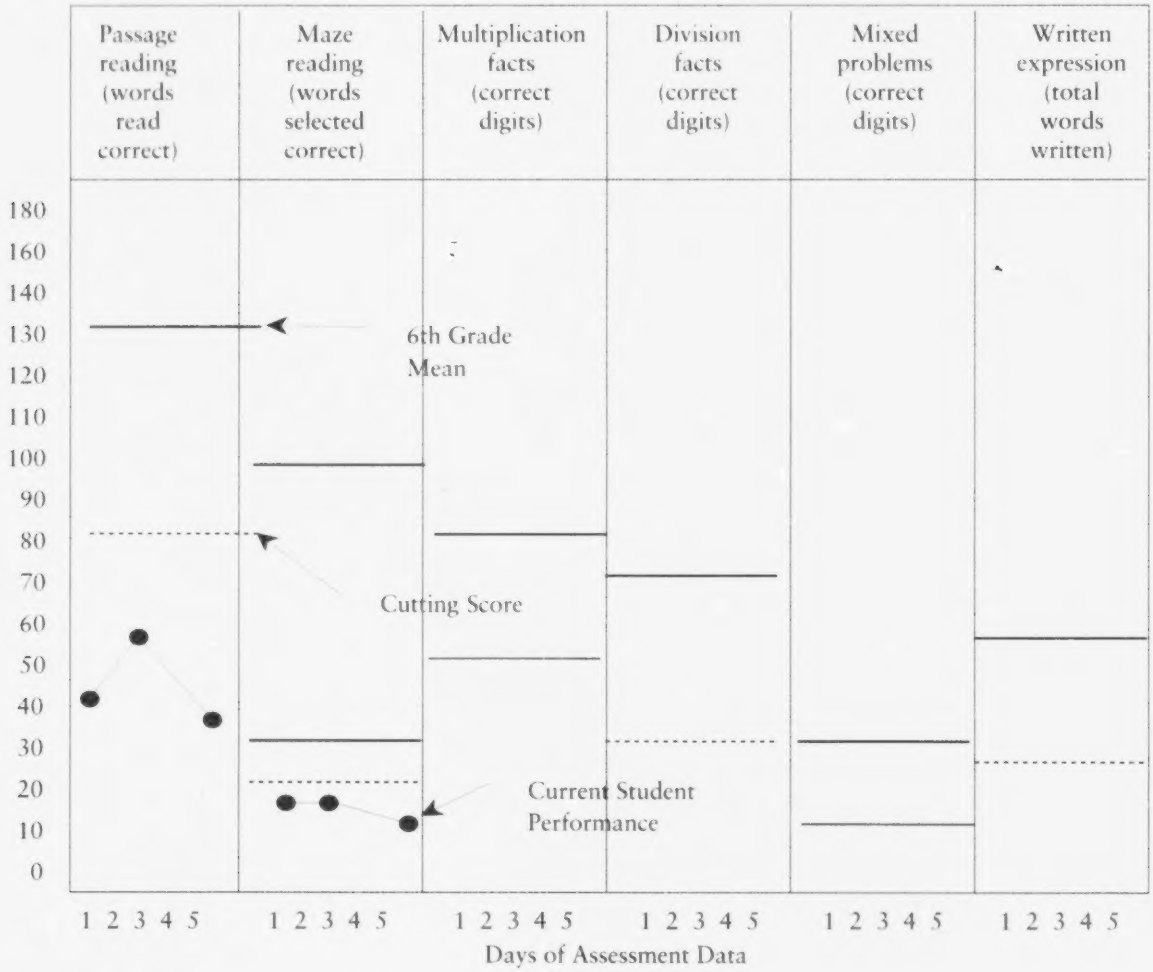
quency polygons can be generated to visualize the norm distribution so it is clear at a glance if the norm data have a relatively normal distribution or one that is skewed.

Percentile ranks are useful when making problem identification, certification, goal setting, and problem-solution decisions. For example, the district may determine that all students who are at or below the *n*th percentile on local norms are in need of further assessment, and students at or below the *n*th percentile are eligible for a particular program. An example of a district percentile rank cut-off chart is presented in Figure 3. In this case the percentiles are represented on a "cut-off" chart that provides a visual display of where a child's performance falls in relation to the local norm. The actual percentile cut-offs used by the district would be determined by considering several factors such as program intent, resources, federal or state guidelines, historical data, and so forth. Percentile rank data may be organized on tables by listing the raw scores and corresponding percentiles for each grade and norming task (Shinn, 1998; Tindal & Marston, 1990).

Percentile ranks also could be used to determine which score corresponds to the spring 50th percentile, and therefore what the goal would be for a student

Figure 3. District norm problem identification cut-off chart: grade 6 (fall)



738

expected to be reading like an "average" student by the end of the year. A useful graphic for representing "typical performance" across grades is presented in Figure 4. The shaded bands represent performance between the 10th and 90th percentile at each grade level, with a line at the 50th percentile at each grade level. This same type of figure could be used to summarize typical performance within a grade across the three norming periods.

Individual student's data and goals can be superimposed on norm data. Figure 5 shows a student's DIBELS phonological awareness "initial sounds" score in September compared to (a) his classmates' scores and (b) research-based benchmark standards. The same figure also shows the goal that was set for the student for February and the aimline toward the goal that the student would need to approximate in order to meet the goal.

Many other types of graphs and tables could be used to organize and summarize the data; only a few of the possibilities have been provided. Regardless of the format chosen, however, having the normative data entered into a computer spreadsheet will make data presentation easier. Some type of computerized data organization and management usually is necessary for building and district norms, and desirable even for classroom norms data presentation. The programming and charting capabilities of spreadsheet programs such as Microsoft Excel™ or AppleWorks™ have been used to organize and summarize local norms data. Some districts and researchers have begun experimenting with collecting the data and providing reports via password-protected internet sites, but these procedures are still under development.

SUMMARY

Although the use of normative comparisons in the schools is common, developing and using local norms as part of a problem-solving system is still a relatively new area for school psychologists. A problem-solving system requires analysis of the educational context as well as the individual student. The context of the educational system—the class size, educational background, socioeconomic factors, student achievement levels, and so forth—will differ from district to district, school to school, and even classroom to classroom. For the school psychologist working with the staff and students in a particular system, local norms can provide a representative sample for local decision

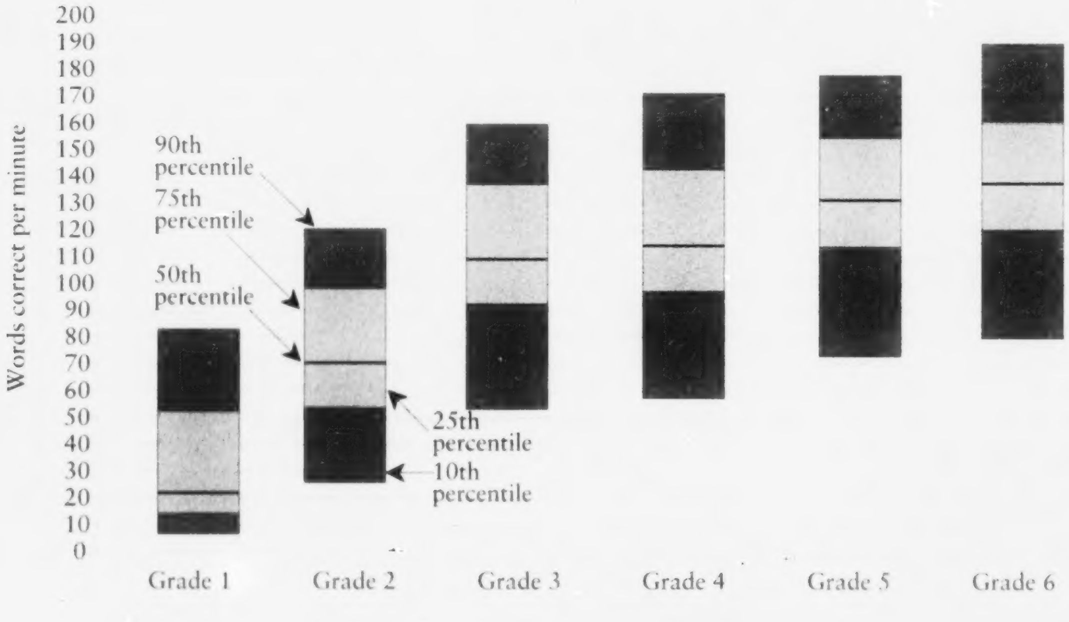

Figure 5. Phonological awareness district norm and benchmark area superimposed with individual student data (September) and goal

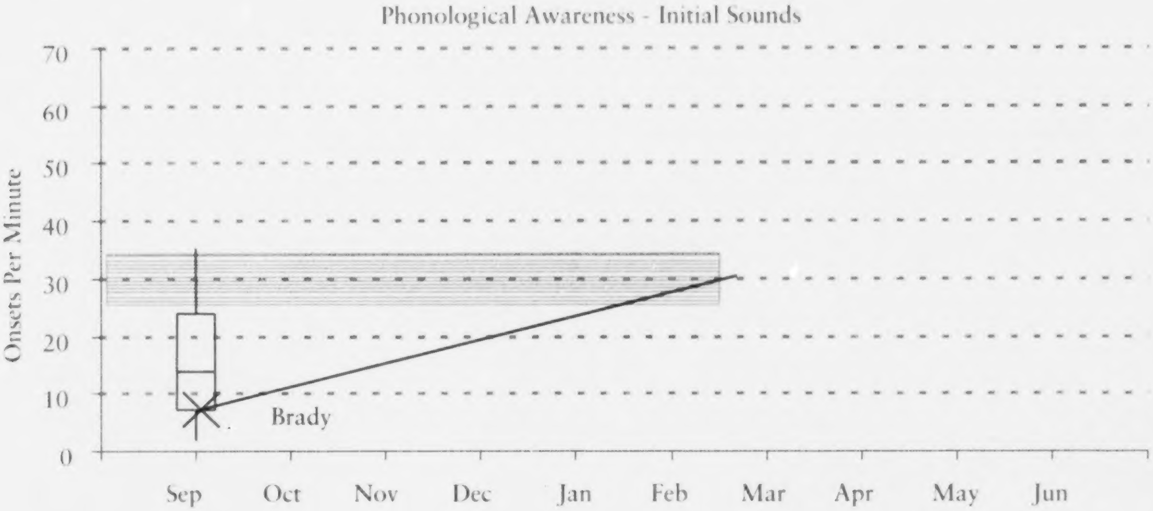

making and offer flexibility in which types of tasks are normed. These characteristics contribute to the strengths of local norms: decreased bias in decision making, increased teaching/testing overlap, and norm utility across educational decisions.

Developing local norms is a process of determining the purpose(s) for norm development, selecting important and valid behaviors to be "normed" and then implementing the five steps of norm development: (a) selecting a level of norm, (b) creating a measurement net, (c) implementing a sampling plan, (d) collecting data, and (e) organizing the data for use. School psychologists have the measurement, communication, and collaboration skills needed to facilitate these steps of local norm development and use.

Local norms can be used to help identify students at-risk of failure and then provide services that prevent problems from occurring. If prevention is not effective, then local norms can be used to (a) identify a problem by determining if a referred student's performance or behavior is outside of the expectations of general education, (b) certify a problem by showing whether the student's performance is so discrepant from peers that special services are warranted, (c) set goals to get the student's performance back within the range of his or her general education peers, and (d) determine when the student's performance is no longer outside of the general education expectations and the problem is solved. Throughout the prevention and problem-solving process, local norms provide a context for making educational decisions.

ANNOTATED BIBLIOGRAPHY

Shinn, M. R. (1988). Development of curriculum-based local norms for use in special education decision making. *School Psychology Review, 17*(1), 61–80.
This journal article describes the development and use of CBM local norms. Applying CBM local norms in special education decision making is presented as an opportunity to expand the role of the school psychologist. Technical adequacy and logistical issues in developing a local database are discussed.

Shinn, M. R. (Ed.). (1998). *Advanced applications of Curriculum-Based Measurement*. New York: Guilford.
This book provides updates on the use of CBM in the areas of pre-literacy (DIBELS), secondary education, assessment of minorities, reintegration, and much more. The chapters provide good background information on the use of CBM with particular populations or for a particular purpose and many chapters include examples of local norm development or the use of local norm data in decision making.

48 Best Practices in Curriculum-Based Evaluation

OVERVIEW

Assessment and evaluation have traditionally been major components of the role of the school psychologist. As schools have engaged in reform efforts, this emphasis on assessment and evaluation and the need to involve school psychologists has not changed, but the types of assessments utilized and the way the information gained from these assessments is used has changed significantly. School psychologists are now being asked to participate in problem solving, analyze both academic and social problem behaviors, and assist in making instructional recommendations based on assessments they have completed.

As schools move from traditional systems of determining placement and services to systems with a problem-solving or solution-focused orientation, the use of functional assessments that can be administered efficiently and then directly linked to instruction is required. To meet these new demands, many school psychologists are seeking the tools and training necessary to analyze problem behaviors and link this analysis to the most appropriate intervention.

In the 1980s Curriculum-Based Assessments (CBAs) emerged as one way to assure that an evaluation would be both efficient and functional. Broadly defined, CBA is the process of determining students' instructional needs within a curriculum by directly assessing specific curriculum skills (Choate, Enright, Miller, Poteet, & Rakes, 1995).

Curriculum-Based Measurement (CBM) is one type of CBA and typically refers to a standardized set of procedures utilized to measure student performance in the areas of reading, math, and written expression (Shinn, 1998). These standardized procedures provide directions for creating, administering, and using tests that have been researched over time and shown to be useful and technically adequate.

This chapter is about Curriculum-Based Evaluation (CBE). CBE can be defined as a thoughtful process of comparison and judgment (Howell & Nolet, 2000). It provides a decision-making framework for considering the assumed causes of a student's academic or social problems, validating these hypotheses, and linking the results to a teaching recommendation.

Because the curriculum-based terminology is so often confused, it seems important to draw a distinction between measurement and evaluation. This distinction is important for an accurate understanding of CBE and of this chapter. To clarify the use of these initials let us provide a bit of entomology. The root of the word evaluate is "value." The "e" at the first of the word is a reduction of "ex" which means "to go forth" in Latin. The "ate" at the end of the word means to find or provide. So "e-valu-ate" means to go out and find the value of something.

In distinction, *measurement* has a more restricted meaning. "Measure" means to gauge, or to find the limits of, a product or quality. The "ment" at the end makes the word one of action (e.g., *to use* a measuring spoon). So measurement means the taking of action in order to determine the limits or extent of something. The term, measurement, has no direct tie to worth or value (it applies equally to important and worthless quantities and qualities). That is its critical difference from evaluation and is why CBE and CBM are distinct.

What is CBE? The heart of a productive CBE is *not* the application of some unique and/or elaborate set of measurement instruments. It is a network of curriculum-driven "If...Then" precepts (an example of this is shown in Figure 17) Each of these are attached to a question and goes something like this:

Question: "Does Mary have difficulty with computation?"

First option: "**If** the answer to the question is *No*, **Then** there is no need for additional questions."

Second option: "**If** the answer to the question is *Yes*, **Then** additional questions are needed."

For example, "Does Mary have skill at basic computational facts?" To find out about these skills, a CBM covering computation facts drawn from the math curriculum will be given and the "If ...Then" sequence repeated:

"**If** the answer to the above question is *Yes*, **Then** higher level computation skills need to be checked."

"**If** the answer to the question is *No*, **Then** additional questions about the sub-skills of computation facts need to be asked."

(Should it prove that these other skills are adequate, then the conclusion would be to teach the computation facts.)

In this fashion, decisions about the knowledge that needs to be examined, as well as that which needs to be taught, are guided by applying the rationale and rules supplied earlier in this chapter. The "If...Then" format becomes the carrier for these guidelines. In addition, the approach uses other formats of inquiry during attempts to answer the questions. It also follows one essential rule.

The rule that underlies all CBE is simple. "If a student can't do something, then it is because the student doesn't know how." The implication of this rule is that the "If ... Then" precepts only deal with things students need to know. Therefore, the precepts focus on potentially missing prior knowledge of the targeted task. This requisite knowledge is the sole focus of the CBE process. The rule tells us to only think about other skills. This forces the process of inquiry, and the subsequent conclusions, to be aligned with the curriculum because the presenting problem is a lack of progress in some aspect of the expected academic or social outcomes (which define the curriculum). Also, because the curriculum is what schools are supposed to teach, the rule forces us to focus only on those things that can be altered by instruction.

Optimally, the CBE format should be combined with an existing system of school-based problem solving and intervention. The process is relatively straightforward. It requires us to answer five questions.

1. *What is the problem and why is it happening?* This is a stage of problem identification and problem analysis that is critical before implementing any intervention. It is carried out to identify missing prior knowledge of the targeted task. It is during this stage that the "If...Then" format is first employed.

2. *What are we going to do about the problem?* An intervention is selected and designed based on the analysis of the problem.

3. *How will we monitor the intervention?*

4. *Is our intervention working?* In this step, data are utilized to make decisions regarding the effectiveness of the instructional strategies and to make a determination as to need for future intervention. (For more information on this problem-solving approach, see Tilly, this volume.) The "If...Then" precepts may again be employed at this level.

5. *If the intervention isn't working, then why is it not working?* This is the step where CBE is most valuable because this is where the nature of the problem is examined and not just monitored.

Basic Considerations

Before moving directly to the application of CBE, it seems like a good idea to review the context in which CBE must be employed. It also seems like a good idea to try and articulate some solutions to problems that often evolve from that context. The evaluation of students with social and/or academic problems is difficult. There are many reasons for this. When students are entitled to compensatory education, efforts to comply with federal and state regulations (along with the misunderstanding from categories, labels, disability theories, and terminology) can create considerable confusion (Zigmond, 1997). As if this were not sufficient, here are some other factors that can contribute to confusion:

1. The sometimes conflicting efforts to explain and improve the learning characteristics of the student.

2. The intricate and still, at times, ill-defined components of the instruction that will be needed to address those learning characteristics.

3. Uncertainty regarding measurements and measures.

4. Confusion about the location and context of service delivery.

5. Misinterpretation of the curriculum (obviously an important concern for CBE). The curriculum is composed of volumes of content, behavior and quality expectations. This amalgamation makes recognizing desirable learning outcomes for singular students hard because finding worthwhile outcomes depend on the evaluator's expertise within the topics of concern.

6. The challenges encountered when individuals from different professional backgrounds work together during the process of problem solution.

The way to work with these confounds is to import order. This can be accomplished by bringing to the problem-solving effort a format for discussion and thought consistent with the original purpose of the effort (Marzano et al., 1988). This format must be logical, flexible, and acceptable to those who will use it. But beyond that, it must be powerful.

Lanfer (1997, p. 61) describes the nature of a functional planning format. These are presented below, and common violations occurring within educational evaluation are provided in italics:

1. "Under conditions of uncertainty, avoid preparing too early a full and detailed plan." An outline plan should be prepared for the entire project and a detailed plan for the short term. *Example error, having teachers prepare IEPs prior to IEP meetings* and/or *scheduling infrequent evaluations of progress towards long-term objectives.*

2. "The outline plan should be prepared with enough flexibility to allow adjustment to a reality that can only be ascertained in the future." *Example error, viewing the contents of an IEP [Individual Education Plan] as if they [the contents] are "locked in" for one year.*

3. "Throughout the course of the project, data must be continuously and actively assembled for future planning." *Example error, "front loading" the measurement and evaluation process by carrying out a massive effort before the plan is developed and then following the plan with minimal monitoring.*

4. "God is in the details, but not too early." *Example error, members of the problem-solving team arrive at meetings having already reached conclusions.*

CBE can provide a logic for working within the contextual disarray of educational decision making while avoiding errors such as those above. CBE is a good process for three reasons:

1. By definition, CBE is aligned with the academic and social outcomes one would select when planning an intervention.

2. CBE utilizes CBM. As will be explained shortly, these are easily administered within classroom, leisure, and/or family contexts. CBM measures are

simple to interpret because they typically yield behavioral statements.

3. CBE is flexible and formative. "Front loaded" decision making is de-emphasized in favor of data collection and decision making across time. This allows for the precise recognition of interventions, an area often ignored when developing formal plans (Bateman, & Linden, 1997).

Barriers to Implementing CBE

Impediments to the use of CBM include:

1. Time required to use the process

2. Concern about validity of the measures

3. Logistics of making a change in common practice

Two of these concerns have now been satisfactorily addressed for those who attend to research findings. Deno (1985) and Martson (1989) have addressed the time issue, and Allinder & Eccarius (1999) have spoken to measurement validity.

This leaves us with the logistics of change itself (i.e., implementation of CBM/CBE). If CBE is as great as we (the authors) say it is, then why doesn't everyone use it? There are many answers to this question. One is that change in evaluation practice is hard to accomplish even when the change is beneficial (Fuchs, Fuchs, Hamlett, & Ferguson, 1992). In a context of competing ideas, change is not simply an issue of adopting new practice. Unless we want to double the workload, some evaluation techniques must be replaced when new ones are added. This means the matter is not as simple as showing that CBE works. It must be shown that CBE works better in terms of utility and/or cost effectiveness (Vaughn, Klinger, & Hughes, 2000). However, there are two reasons why this may be difficult to accomplish: (a) The inertia found in almost all systems makes them hard to change. Additionally, even when a great deal of pressure is applied, organizations do not typically change quickly. They are even apt to tighten existing structures in the belief that the system is correct but not being run effectively. This same outcome can result from the perception that the system is not adequately "appreciated" (Spinoza, Flores, & Dreyfus, 1997). (b) In education and school psychology collective inertia can extend from federal offices down through professional organizations and then on to publishers and other marketers of evaluation technology and into school districts, schools, and eventually classrooms. This makes it difficult for individuals or groups working at any point in the series to undertake efforts at effective change. Collective inertia in the area of psycho-educational evaluation is not the result of missing empirical results or the lack of efforts at innovation (see Tilly, this volume). However, some causes can be identified.

THE SUPREMACY OF MEASUREMENT

Change may be inhibited when we focus on the tools of measurement (and the scores they yield) at the expense of the processes of problem solving. This is why we draw a distinction between CBE (a thoughtful process of comparison and judgment) and CBM (a process of measurement and data collection). Gould (1981) cautions against the fallacy of "reification," which he defines as ". . . the tendency to convert abstract ideas into entities." (p. 24). Similarly Kaplan (1964) has referred to the "mystique of quantity," which he defines as ". . . an exaggerated regard for the significance of measurement, just because it is quantitative . . . " (p. 72). Kaplan goes on to assert that in this mystique, "Number is treated as having an intrinsic scientific value." In CBM, numbers only have meaning if they inform CBE.

In a complex system, whenever one person sets out to change, that person is not just undertaking personal change but is setting out to alter the system. Within psycho-educational evaluation there are components, and within each sub-system (test administration, personnel training, service delivery) there are people who believe different things. If two different people in the same system hold two different, and competing, opinions about the goal of the assessment, then it is disruptive. This sort of situation reinforces personal inertia. The solution, of course, is to unite people under the system's purpose and to utilize differences of opinion as a strength (e.g., to promote flexibility). Lanfer (1997) recommends specific remedies to address this problem:

1. Work to assure that individuals think they *can* work efficiently and that they *should* work efficiently.

2. Give individuals and subgroups power so that they become committed to a system *they* have helped develop.

3. Establish high expectations for each person in the system.

4. Ensure that each person understands the importance and meaning of his or her contribution.

5. Allow individuals the flexibility and autonomy needed to trouble shoot problems and to make the system more efficient.

6. Make the system "transparent" so each person knows what everyone else is doing.

Making the system transparent seems particularly appropriate to the role of CBE within psycho-educational evaluation. For this discussion, transparency means not only that each individual on the evaluation team knows what every other individual is doing but that they also understand what every other individual is doing. *They do not have to like it, but they must understand it.* This is because the final product is a team product, not individual. Similarly, other teams working to help the student must also be transparent to the evaluation team. Yet it is a mistake to assume that simply putting the members (or teams) together will somehow promote this transparency. The experience of those of us who have served on teams can attest to that. The requirement that individuals with different backgrounds in evaluation work together does not, in and of itself, produce interdisciplinary understanding and cooperation. It only requires proximity. Work must be done to assure that teams operate well. Information on the development of effective groups can be found in the chapters on teams and collaboration in this book. Relative to this chapter, support of effective use of CBE within team formats can be facilitated by administrators who support CBE with training for current employees. In addition, personnel departments should screen new applicants for competence in CBE.

The purpose of this discussion of problem solving for removing barriers to innovation will become clearer in the section that follows. But it is important to know that the technology of CBE is not new. For example, important work pertaining to direct measurement and formative evaluation can be found in sources such as Deno and Mirkin's (1977) work on data-based program evaluation. That work is more than 20 years old, and the principles and techniques presented in it are still not common practice.

BEST PRACTICE

Best practices in the use of CBE can most effectively be presented through a case study. In this case we have selected "reading" as the problem domain. Because of length considerations this will be the only content area covered, although the same process can be applied to a wide array of academic and social skill content. Those readers interested in social skills should read the chapter by Knoster and McCurdy in this volume. Other sources of information include McLoughlin & Lewis (2001) and the Center For Collaborative Research and Practice (http://www.air-dc.org/cecp/).

We will now review a case in which CBE was utilized to make instructional decisions for a student. The student is Susan.

BACKGROUND INFORMATION

Susan is a third grader at an elementary school we will call Happy Valley Elementary. Happy Valley Elementary is a small school in a district in Iowa on the outskirts of a metropolitan area of approximately 500,000 people. The student population is about 400 students with 26% eligible for free or reduced lunch because of low-income levels.

Happy Valley Elementary uses the problem-solving approach developed by Heartland Area Education Agency (2000) to address the needs of students at various levels of severity.

Susan has attended Happy Valley since she started kindergarten. She has not been retained, but her records indicate that reading and writing skills have been consistent areas of concern. In the fall of her third-grade year, Susan's teacher noted that Susan's reading performance was far lower than that of her peers and that her oral reading was slow and laborious. Susan also made many errors.

AN INITIAL ATTEMPT

The teacher and Susan's mother discussed the problem and decided to have Susan read at home every night for 15 minutes from books the teacher would select and send home on a regular basis. Susan was in the Title One Remedial reading program, and the Title One teacher routinely kept oral reading fluency data (number of words read correctly per minute) by using CBM procedures on all her students. Susan's progress was charted and graphed, and these data were available to the general classroom teacher and parents. After trying their plan for a while, Susan's teacher and parents were not satisfied with her reading progress and decided to make a referral to the Building Assistance Team (BAT).

BUILDING ASSISTANCE TEAM

At Happy Valley, the teachers at each grade level form a team that meets when needed to engage in problem solving. The third-grade BAT determined that it would be appropriate for Susan to be placed in a reading group that was taught collaboratively in the general education classroom by the special education teacher and the general education teacher. At the time there were several students in the class who were identified as students in need of special education and who had IEPs with goals in the area of reading. The IEP team had determined the most appropriate service-delivery model for those students was to provide instruction in the general classroom with the special education and general education teacher co-teaching. Reading materials at her instructional level were used. In addition, the teacher began using Peer-Assisted Learning Strategies (Simmons, Fuchs, Fuchs, Hodge, & Mathes, 1994). This provided Susan with additional practice reading and feedback from a peer coach.

CBE

Later, the third-grade BAT reviewed the CBM monitoring data collected by the Title One teacher and again determined that Susan's progress was still not sufficient. At this point the BAT decided to involve the school psychologist.

The BAT had already defined oral reading fluency as the problem behavior, and there appeared to be no need to further define the problem. It was determined, however, that additional analysis of the problem was needed. This is where full CBE was used. During problem analysis, the problem-solving team is trying to answer the question, "If current interventions are not working, then why aren't they working?"

A CBE will lead the examiner through a decision-making process that will guide the examiner to propose a series of curriculum-based hypotheses as to why the problem is occurring. Each question or hypothesis will focus on missing prior knowledge of the oral reading task. This hypothesis is then validated or discarded. Once a hypothesis has been validated, then the intervention(s) that will most likely address the problem will be identified. Figure 1 provides a flowchart illustrating the process of CBE used for the area of reading decoding and, at the end of the presentation, Figure 17 provides a summary of the precepts employed during that process. It also contains general information about the terms which will be used throughout the upcoming discussion. In Figure 1, the arrows indicate the path followed in this evaluation. All procedures described as part of this process have been adapted from Howell and Nolet (2000).

Evaluation and explanation

Susan's case will be presented in the form of the actions that were taken during the evaluation and the questions that were answered throughout the decision-making process (see Figure 2).

ACTION 1: SURVEY READING SKILLS

As seen in Figure 2 the whole process starts out with what follows:

> Question. Are oral reading skills acceptable? If "yes," then the decoding evaluation is discontinued. If "no," then the student's current level of performance is noted and the next question is asked.

To answer this question, the school psychologist began by using survey-level assessment procedures. Survey-level procedures are initial assessments conducted to collect a general sample of behavior. These assessments guide further assessment. The sample is also used to determine whether or not the magnitude of the problem warrants further evaluation. These procedures can consist of reviews, interviews, observations, or tests (RIOT).

The first survey-level procedure used in Susan's case was a teacher interview. During this interview the teacher was asked to consider some specific prerequisite reading skills and indicate if the skill had been taught, whether the student demonstrates the skill, or if it is considered a problem. The school psychologist needed this information so that she would not spend time assessing prior knowledge the student could not be expected to demonstrate because it had never been taught. There were numerous skills the teacher indicated had been taught and were considered problem areas for Susan. The skills the teacher identified as problems were in both decoding and comprehension. Also, during the interview the teacher was asked to consider the demands of the setting and whether or not there was anything in the environment that may be interfering with the student's benefit from reading instruction. The teacher did not identify any interfering factors in the environment. The next survey-level procedure used in Susan's reading evaluation was CBM of oral reading. The Title One teacher had been monitoring Susan in third-grade reading material since the beginning of the school year; therefore, the school psychologist had access to the data and did not need to carry out additional assessment. (Another rule of evaluation is to never assess if other current data are available from a reliable source.) According to progress monitoring data, Susan was reading 37 words correct per minute with 78% accuracy.

Given this information the school psychologist developed a new, but related, evaluation question. *Was Susan's oral reading adequate when given easier passages?*

If a student's accuracy and fluency improves on easier passages, **Then** there may be sufficient skills to support teaching within the context of passage reading.

New information, beyond the Title One records, is needed to answer this question. So Susan's reading was assessed with second-grade passages. Susan read 65 words correct per minute with 80% accuracy in second-grade–level material. This means her rate did improve, but not to the 100 words per minute (wpm) criteria. Once again, this information was important because it indicates that Susan does have sufficient prior knowledge of letter-sound associations to

Figure 1 is a flowchart. So that you can better understand it, here is a brief explanation of its content.

- An ellipse is a question that an evaluator should ask;
- The answers to the questions are noted on the lines;
- A rectangle is an action that must be taken; and,
- A rectangle with a number on the side (e.g. "7") is a decision to try, and to monitor. It is a teaching recommendation.

Are reading skills acceptable?

decode some material. Something is standing in the way of her attainment of sufficient automaticity in reading. We will return to this finding after finishing the survey process.

The next step in Action 1 was to review records and permanent products. There were few permanent products to review, although several samples of her writing were reviewed, which indicated numerous spelling errors even on short, consonant vowel consonant words.

When the school psychologist reviewed records she found that in the past a special program targeting at-risk readers had served Susan. Test scores in her file included the California Achievement Test (CAT) given in the spring of second grade. Her verbal scores were at the 27%, quantitative 23%, non-verbal 69%, and composite 40%. Iowa Test of Basic Skills scores from winter of third grade indicated reading 5th percentile, language 33rd percentile, and math 40th percentile according to Iowa norms.

The school psychologist also reviewed hearing, vision, and health records to rule out any sensory or health impairments that may be interfering with learning. Vision and hearing had been screened earlier in the year, with normal results. Susan's health records had not been updated for over a year, so the school nurse called the parent and inquired about any health concerns. Susan's mother indicated that Susan did not have any health problems related to reading. As a result, any focus on health problems was set aside until if, or when, new information was obtained.

The final survey-level assessment was a review of the curriculum and the instructional materials at Happy Valley Elementary in Susan's class. In Iowa, each school district develops its own standards and benchmarks. Happy Valley's district was in the process of completing standards and benchmarks in the area of reading. By reviewing materials that were currently being used by the teacher, it appeared that although Susan had received skill instruction on specific decoding skills, it had not been provided in any particular sequence. The reading material being used in the classroom was drawn from children's literature, and this might be a problem because the vocabulary in this literature is infrequently controlled (Adams, 1990). This is problematic because, without a clear understanding of what is to be taught, quality instruction is not possible (Price & Nelson, 1999).

INTERPRETATION OF ACTION 1

Survey Reading Skills Question. Look at Figure 3. In the sphere the question "Are oral reading skills acceptable?" is asked. The answer was "no," so the student's current level of performance is noted and the next question is asked.

Because the student's reading was unacceptable, the next step under Action 1 was to summarize the magnitude of the problem.

The Heartland criterion for grades three and above is that students should read 100–140 wpm. Susan correctly read 37 wpm. According to this standard, her oral reading is not acceptable. Another standard is to compare Susan to typical peers in her school district. The district had established local norms by using CBM several years ago. The median score for third graders according to district norms is 121 wpm. Susan's score of 37 wpm falls at the 8th percentile rank. According to this standard, her reading rate is also not acceptable. Figure 4 illustrates Susan's performance compared to same grade peers in her school district.

Figure 3. Determine discrepancy in oral reading

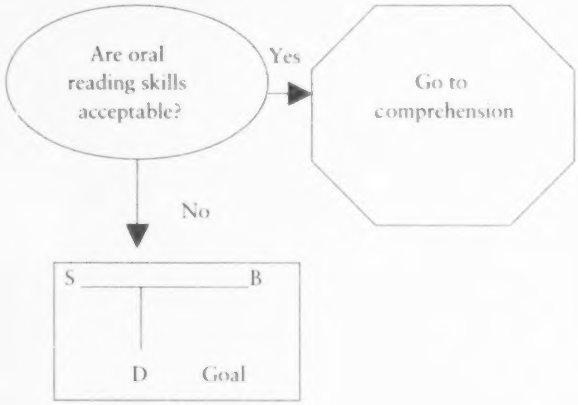

Figure 4. Susan's place in a score distribution

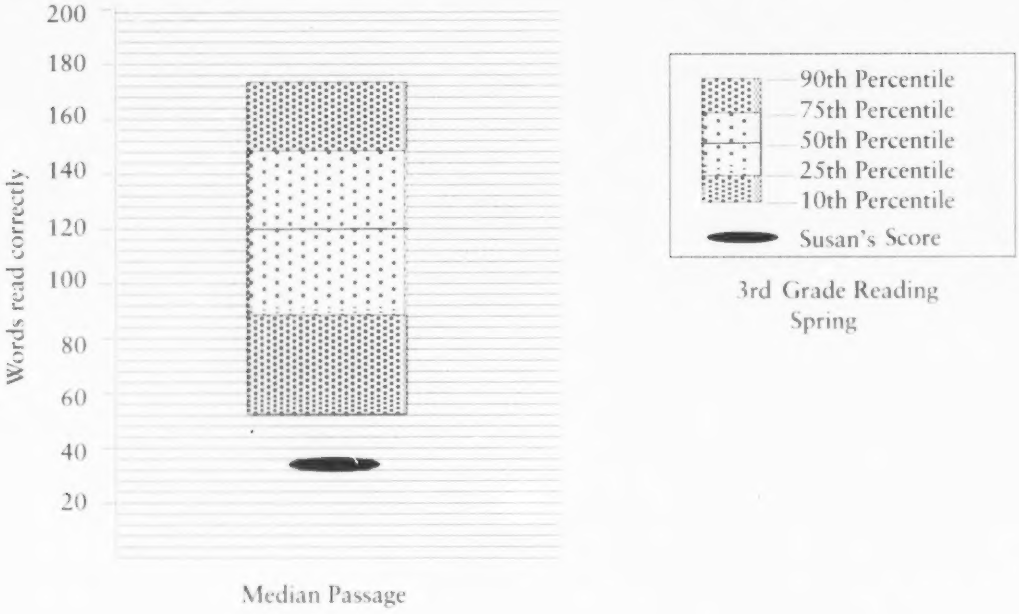


If oral reading had been acceptable, **Then** it would have been more appropriate to consider an evaluation of comprehension skills. However, the answer to the question raised in Figure 3 was "no." Since oral reading fluency can be thought of as one prerequisite of comprehension (along with knowledge of word meaning and content), the school psychologist decided to continue to examine Susan's speed and accuracy of decoding (Committee on the Prevention of Reading Difficulties in Young Children, 1998).

Before continuing with the evaluation, Susan's goal was formalized by using the following formula provided in Figure 3.

standard 100 – behavior 37 (Susan's Score) = discrepancy 63

The goal is to improve Susan's oral reading by 63 wpm.

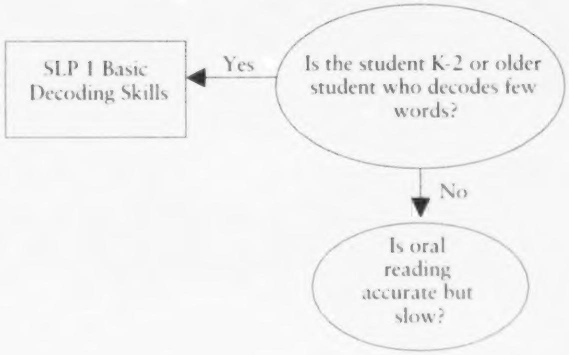
The standard the school psychologist used was the marginal passing score recommended by Howell and Nolet (2000). Susan's goal was to increase her reading fluency by 63 wpm to 100 wpm. To do this, the evaluation had to be continued to check assumptions about missing prior knowledge that might be causing her reading difficulties. After the survey-level assessment the school psychologist needed to consider which of the Specific Level Procedures (SLP) to use. Because of Susan's low performance the evaluator decided to use SLP 1 (awareness of print and sounds) before following the flowchart directly to SLP 3 (assisted monitoring).

ACTION 2: ASSESS BASIC DECODING SKILLS

Question. Next look at Figure 5. (a) Is the student in kindergarten or first grade. (b) Does the student appear to be very low in the use of decoding skills? If "yes" to either, then the student's basic decoding skills need to be checked. If "no," then the student's rate and accuracy when re-reading needs to be determined.

Because the answer was "yes," it was decided that basic decoding skills should be checked by using SLP 1. These basic skills have been called many different things. In the literature they are said to include knowledge of the alphabetic principles, including phonemic and phonetic skills, that go all of the way from letter/sound discrimination to decoding three-letter words (Committee on the Prevention of Reading Difficulties in Young Children, 1998). Some call them "pre-reading" skills while others simply call them "reading skills." They are distinct from previ-

Figure 5. Consider the age of the student



SLP 1 Basic Decoding Skills

Is the student K-2 or older student who decodes few words?
No
Is oral reading accurate but slow?

ous efforts to define early reading content in that they include letters and/or letter sounds (not circles or boxes or train whistles or eye patches).

These basic skills provide a foundation necessary for reading success in that the more we know about letter-sound associations (phonics) the better we are able to manipulate written language within our head. Typically, these skills are established by the end of kindergarten (Perfetti, 1985; Good, 1999). In most cases they are learned along with phonics instruction itself. Therefore, a "pure" measure of phonological awareness would only be given to a student in preschool or kindergarten. However, as with all skills, an important proficiency dimension applies to this category. That is *automaticity*. In this case the evaluator is wondering if Susan has the skills needed to maintain rate and accuracy when using basic phonological and phonetic skills. In her interview with the teacher and her examination of the curriculum, it was evident that Susan had never received explicit instruction in phonemic or phonetic skills. Second, examination of Susan's spelling errors indicated that she did not consistently associate letters with each sound in the word she was attempting to spell. Finally, Susan appeared to only be recognizing sight words while making errors on words requiring decoding skills. Therefore, although on the basis of her age one would expect Susan to have adequate basic reading skills, the school psychologist decided to go ahead and assess this area and used what follows as a logical consideration:

1. Susan seems to be accurate at all of the basic skills but is still too slow.
2. There is a difference between knowing a skill and efficiently connecting it to practice.
3. So, Susan needs to have her automaticity on some basic reading skills rechecked.

The results of this assessment are displayed in Figure 6.

Susan was accurate and at least marginally fluent in all skills. If this assessment had indicated missing beginning reading skills, then the school psychologist would have made a recommendation to teach knowledge of these skills as part of Susan's instructional program. However, the assessment indicated that Susan had the basic foundational skills necessary to read. And, on the skills where fluency was somewhat low, the rate would probably be better increased through passage reading. Therefore, the question raised in Action 2 is interpreted as follows.

INTERPRETATION: ACTION 2

Assess Beginning Reading Skills Question. Next look at Figures 7 and 8. Is the student in kindergarten or first grade, or does the student appear to have very low decoding skills? Answer is "no."

This means more assessment will be needed to determine the cause of Susan's reading difficulty.

ACTION 3: ASSISTED MONITORING

Question. Figure 8 shows the path to SLP 3. In turn, SLP 3 leads to the question, "Will the student's accuracy improve after being given assistance to monitor errors?" If "yes," then instruction on the use of self-monitoring (decoding treatment 6) will be needed. If "no," then an error sample will need to be elicited.

Two simple procedures were utilized to determine if Susan would monitor errors when assisted. The first of these procedures is simply a pep talk. The school psychologist gave Susan another passage from the third-grade curriculum. This time Susan was told how important it was to do her very best reading. She was encouraged to read accurately. The second procedure used is called the table tap. Susan was given another passage to read and was told that every time she made an error, the evaluator would immediately tap the table with her pen. This would be Susan's cue to go back and correct errors. Susan's accuracy did not improve with either procedure. It appears that even with assistance Susan does not monitor and cor-

Figure 6. Accuracy and rate criterion for various code skills

Skill	Compound Words	Syllables	Sounds
Blending from print	93% Marginal rate	95% Marginal rate	100% Adequate Rate
Sound/letter correspondence	96% Marginal rate	100% Adequate rate	100% Adequate rate
Blending sounds (blending sounds, syllables, or words to make new words). Example: s^u^n = sun, ti^ger = tiger, tip^toe = tiptoe.	100% Adequate rate	100% Adequate rate	100% Adequate rate
Segmenting sounds (breaking a word apart into sounds, syllables, or smaller words). Example: sock = s^o^ck, table = ta^ble, cowboy = cow^boy.	100% Adequate rate	100% Adequate rate	100% Adequate rate
Sound deletion (deleting sounds, syllables, or small words from words). Example: What would be left if I took "f'" away from farm?	100% Adequate rate	100% Adequate rate	100% Adequate rate

rect her errors. Therefore, further evaluation is needed.

INTERPRETATION: ACTION 3, ASSISTED MONITORING

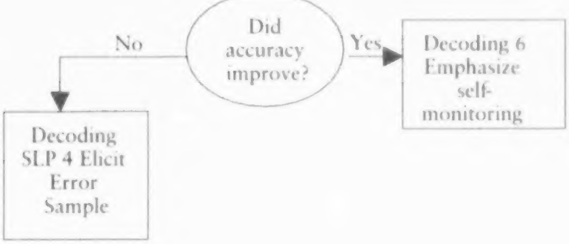
Question. Did accuracy improve? Answer is "no." This means that the evaluator needs to go on to SLP 4, as seen in Figure 9.

ACTION 4: ELICIT AN ERROR SAMPLE

Question. Might the student errors harm meaning? If "yes," then go to SLP 5. If "no," then go to teaching recommendation 1 as shown in Figure 10.

To answer this question the school psychologist gave Susan more passages to read orally so that the school psychologist could collect a sample of Susan's errors. The school psychologist selected a 250-word

Figure 9. Determine if assistance improves accuracy



Did accuracy improve?
No
Yes
Decoding 6 Emphasize self-monitoring
Decoding SLP 4 Elicit Error Sample

passage that she predicted Susan would read with 80–85% accuracy. The passage level was determined by referring to the results of Susan's survey level assessment.

It is important to use passages in which the student is about 80–85% accurate. If more accurate, then it would not be possible to gather enough errors (as was the case on Susan's survey-level passage). If the passage promotes too many errors, then it would be impossible to categorize and look for error patterns, because, when many errors occur, they often reflect as much guessing as they do decoding. Collecting 50 errors is recommended for a student Susan's age.

Susan was instructed to take her time and to read carefully, because this action is not about rate but rather accuracy. When CBM procedures were used earlier during survey-level testing, each time Susan hesitated for more than 3 seconds the school psychologist told Susan the word. For this measure Susan was encouraged to read every word, and no words are supplied. The evaluator used a tape recorder so that she (the evaluator) could go back and listen to check the scoring. (Note: If, after reading the first 20 words of the passage, Susan had not been near 80–85% accuracy, then the school psychologist would have discontinued and selected a different passage.) The school psychologist marked the errors so that she could categorize them later if needed. See Figure 11 for an example.

In Figure 11, *children* was mispronounced as *chick*, *flowers* was mispronounced as *flown* but then self corrected, *the* was omitted, and *to* was inserted.

INTERPRETATION: ACTION 4, ELICIT ERROR SAMPLE

Question. Did student errors compromise meaning? The answer is "yes," so, as seen in Figure 12, errors need to be categorized.

Figure 10. Determine if the skills maintain as passages get harder

Yes
Do errors harm meaning?
Decoding SLP 4 Elicit Error Sample

ACTION 5: CATEGORIZE ERRORS

Question. The question in Figure 13 is "Are there patterns?" If "yes,", then employ decoding intervention 5. If "no," then go to SLP 6.

The school psychologist began to categorize the sample of 50 errors obtained earlier. She used the form shown in Figure 2. The first question she asked was, "Do errors in decoding impair Susan's understanding of the passage?" To answer this question the school psychologist took each error and placed it into

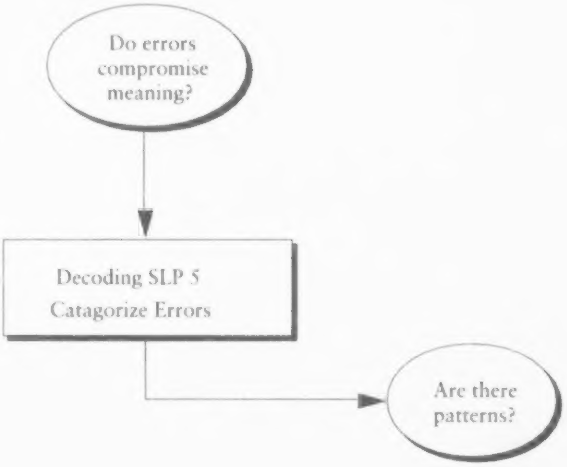
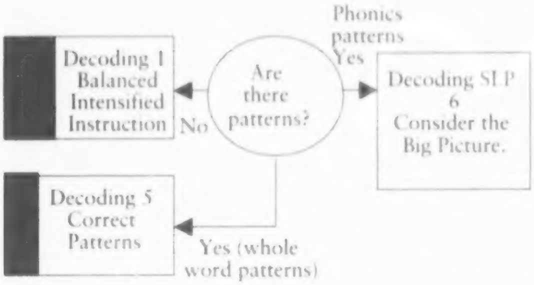
The children went up the hill to see the goats and pick flowers.

Figure 12. Determine if errors alter the meaning of the passage



Do errors compromise meaning?
Decoding SLP 5 Catagorize Errors
Are there patterns?

Figure 13. Determine if there are error patterns



one of two categories, those errors that violated the meaning of the author and those that did not. **If** Susan's errors were not likely to affect her understanding of the passage (e.g., omission of the words *not* in this sentence), **Then** they would not be considered important errors. They could be ignored.

Susan's errors were important errors in that they significantly altered the meaning of the passage and could not be ignored. For example, reading *chick* for *children* and *flown* for *flowers* changes the meaning of the passage. Therefore, further analysis was performed. Next, patterns to errors, such as like insertions, substitutions, hesitations, or omissions, are considered. These are error types that do not necessarily include phonetic mistakes. In this case the question was, "Do the errors fall into certain patterns?"

The final step in the analysis was to determine if specific code content errors were occurring.

INTERPRETATION: ACTION 5, CATEGORIZE ERRORS

Question. Are there error patterns? Answer is "yes." The majority of Susan's errors violated the meaning of the text. Susan's errors indicated that she was not consistently recognizing longer sight words in passages and was having difficulty applying decoding rules and strategies to words of all lengths. Susan also had difficulty with words if they contain b's and d's. **If** there had been no patterns to the errors and no decoding errors, **Then** the school psychologist would have recommended balanced instruction. **If** there were error patterns (e.g., substitutions) without phonics errors evident, **Then** the school psychologist would have gone to teaching recommendation 5 to correct the error patterns. Since there were phonics errors, she decided to step back and consider the big picture (SLP 6).

ACTION 6: CONSIDER THE BIG PICTURE

Question. As seen in Figure 14, the question is, "Is an emphasis on phonics justified?" If "yes," then, Susan will go to decoding recommendation 7. If "no," then Susan will go to SLP 7.

SLP 6 involves gathering all the data collected up to this point and considering whether or not phonics should be emphasized. The pieces of information allow the school psychologist to answer the following question, "Are there decoding skills this student needs to learn to be a successful reader?"

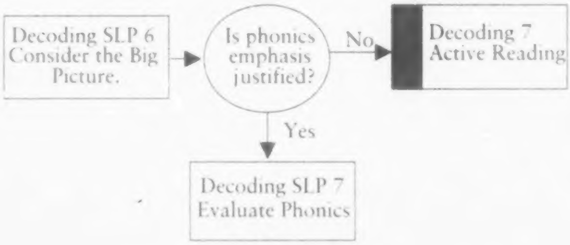
1. What was the most fundamental error pattern? The error analysis indicated that there were significant decoding errors. More examples of these errors are needed to determine exactly what skills need to be taught.

2. In the area of reading what has been taught and how has it been taught? During the survey-level assessment, the school psychologist had performed an analysis of the curriculum used in the district and found some problems with the sequence of skills taught. Beyond that, it was unclear as to whether or not the standards and benchmarks outlined by the district were being adhered to in Susan's class. This is a very difficult judgment to make and involved more in-depth interviews with teachers.

3. What is the student's age? Susan is currently a third grader. She is relatively young and has not had numerous years of direct instruction in a code emphasis approach.

4. What is her current level of performance? She is accurate at basic decoding but lacks automaticity. There are many decoding errors in her oral reading.

Figure 14. Determine if the focus should be on phonics



INTERPRETATION: ACTION 6, CONSIDER THE BIG PICTURE

Question. Is an emphasis on phonics justified? Answer is "yes," as seen in Figure 15.

If the school psychologist had decided that a code emphasis approach was not warranted, then she would have recommended working with Susan to become a more active reader. Instead, the school psychologist thought about each of the factors described above and decided to go on with an evaluation of phonics.

ACTION 7: EVALUATE PHONICS

Question. The other side of Action 7, as illustrated in Figure 1, is the decision about which other categories of code content should be included in the student's instructional program? This question is illustrated in Figure 16. If a particular category of content is recognized, then that category should be taught.

The school psychologist had already decided to emphasize phonics, so at this point she tried to determine what decoding content to target. She decided to assess sight words, additional decoding errors, and then some sound errors (blending had been ruled out with SLP 1). To assess sight words, she used several sight word probes, and to assess decoding errors she used probes from the Multi-Level Academic Skills Inventory-Revised (MASI-R) (Howell, Zucker, & Moorehead, 2000). She used pseudo-word probes from the MASI-R to assess decoding errors. It was important for her to use pseudo-words so that she could isolate the sound-letter associations Susan needed to learn without concern that Susan had memorized the words. Students can have whole words committed to memory but at the same time lack the skills to deal with some of the letter-sound association within those words. The remainder of the flowchart was passed over because the school psychologist decided she had adequate information to go on to teaching recommendations.

Conclusion

The school psychologist reviewed all the assessments that she had completed. By following an evaluation process based on the assumption that Susan was missing knowledge of essential portions of the curriculum, the school psychologist recommended that Susan's teacher use the teaching recommendation labeled "decoding 2." This would allow the teacher to assist Susan on short vowels in combination with silent *e*, vowel teams, and common endings or suffixes (*ed, ing, ler, ly*). The school psychologist pointed out that Susan would benefit from direct instruction in materials that would present these skills in an appropriate sequence (Stein, Carnine, & Dixon, 1998)and further indicated that instruction would need to be followed up with practice aligned with the instruction so that mastery is reached. This same level of material should be used with the teaching recommendation labeled "decoding 8" to provide the practice needed for sight words.

Finally, close monitoring of growth in fluency and accuracy of oral reading would need to be employed to judge the effect of these recommendations.

SUMMARY

This chapter has outlined the rationale, and process, of CBE. Most of the chapter was allocated to the presentation of a sample evaluation. Throughout this evaluation the thought processes of the evaluator were displayed to illustrate how one moves through the course of problem solving when working in this model. A flowchart of the decoding decision-making process, which is used daily by those working at the Heartland Area Education Agency, was displayed to help the reader understand the practice. In Figure 17 the same information was supplied without the format of a flowchart. Similar processes have been developed for computation, language, written expression, social behavior, and task-related behavior. In each case the use of curriculum-based thought process, combined with the use of multiple-data sources, has led to evaluation reports of great utility. The principle factor leading to this utility is an assumption. It is that students fail at academic and/or social tasks because of missing knowledge and not because of biological or psychological disorders.

CBE are conducted to determine what to teach and how to teach it. By using tools such as those illustrated in this chapter along with a decision-making framework to guide assessment will enable school psychologists to play a vital role in problem solving and planning for the instructional needs of children.

Figure 17. Precepts of reading evaluation

If: oral reading skills are acceptable	**Then:** go on to comprehension
If: oral reading skills are not acceptable	**Then:** consider the age and accuracy of the student
If: the student is K-2 or an older student who decodes few words	**Then:** check basic decoding skills
If: basic decoding skills are unacceptable	**Then:** focus instruction on the missing basic decoding skills (use decoding 3)
If: basic decoding skills are acceptable	**Then:** use assisted monitoring to see if the student can correct his or her own errors
if: the student is above grade 2 or above and decodes fairly well	**Then:** check to see if oral reading is accurate but slow
If: If oral reading is inaccurate	**Then:** use assisted monitoring to see if the student can correct his or her own errors
If: oral reading is slow but accurate	**Then:** see if the student's rate improves when re-reading
If: the student's rate increased by about 40% on second reading	**Then:** use decoding 4, build fluency
If: the student's rate did not increase by about 40% on second reading	**Then:** elicit an error sample
If: you have used assisted monitoring and found that the student does not correct his or her own errors	**Then:** emphasize self monitoring (decoding 6) through instruction
If: you have used assisted monitoring and found that the student does correct his or her own errors	**Then:** elicit an error sample
If: the student's errors do not increase as the passages get harder	**Then:** use decoding 1, balanced reading instruction
If: the student's errors do increase as the passages get harder	**Then:** categorize Errors
If: there are no patterns to the errors	**Then:** use decoding 1, balanced reading instruction
If: there are whole word error patterns	**Then:** correct the patterns using decoding method 5
If: there are phonics error patterns	**Then:** consider the big picture

(Figure continues on the following page.)

Figure 17. (continued)

If: phonics instruction does not seem indicated	**Then:** use active reading instruction (decoding technique 7)
If: phonics instruction does seem indicated	**Then:** do a thorough evaluation of the student's knowledge of phonic skills
If: there are sound and blending errors	**Then:** emphasize decoding skills (decoding intervention 2)
If: If there are sight-word errors	**Then:** include sight words in the instructional program (using decoding 8)
If: the student seldom self-corrects meaningful errors	**Then:** emphasize self monitoring (decoding 6)

This book represents the work of various authors from around the nation who have had direct experience with special education reform. In addition to other pertinent information on functional assessment, chapters are included on noncategorical services for students with severe disabilities and methods for finding solutions to educational problems.

Shinn, Mark. (1998). *Advanced applications of Curriculum-Based Measurement*. New York: Guilford.
CBM is a critical component of a CBE in the areas of reading, math, and written expression. This book provides updated information on the use of CBM within a problem-solving model. Among other topics, assessment of early literacy skills in a problem-solving model is addressed in a chapter written by Roland Good III and Ruth Kaminski.

Tindal, G., & Marston, D. (1990). *Classroom based assessment: Evaluating instructional outcomes*. Columbus, OH: Merrill.

This book provides information on classroom-based assessments that integrate testing and decision making. The book is organized into three areas. First, general measurement concepts are outlined. Next, specific assessment strategies in the basic skill areas are provided, and, finally, three evaluation strategies that compare student performance to peers, a standard, or previous individual performance.

49 Best Practices in Increasing Academic Learning Time

Maribeth Gettinger and Jill K. Seibert
University of Wisconsin-Madison

OVERVIEW

How children spend their time in classrooms continues to be a topic of importance for teachers, school psychologists, administrators, and educational researchers. Recently, researchers concluded that as little as half of each school day may be devoted to instruction in some classrooms, and engagement rates among students may range from as low as 50% up to 90%, depending on teachers' managerial competencies, type of instruction, grouping practices, or individual student characteristics (Hollowood, Salisbury, Rainforth, & Palombaro, 1995).

Interest in learning time can be traced to Carroll's (1963) original model of school learning, which hypothesized that learning is a function of time engaged relative to time needed for learning. The earliest and most extensive research program to examine the relationship between learning time and achievement was the Beginning Teacher Evaluation Study (BTES) (Denham & Lieberman, 1980). The purpose of BTES was to identify teaching activities and classroom conditions that promote student learning. Based on observations in classrooms over a 6-year period, BTES researchers arrived at the concept of *academic learning time* (ALT). Briefly, ALT is the amount of time during which students are actively, successfully, and productively engaged in learning (Fisher & Berliner, 1985). Perhaps the most significant finding from the BTES project was that ALT is a strong determinant of academic achievement.

Among the many variables that contribute to student achievement, ALT has been accorded special significance by educators because of the significance of the BTES findings and because components of ALT are viewed as manipulable facets of classrooms that teachers may be able to control. Research on effective teaching has identified evidence-based practices that strive to maximize learning time for all students (Gettinger & Stoiber, 1999). Given the significance of time as a determinant of learning, the purpose of this chapter is to describe best practices for working with teachers to evaluate, extend, and enhance ALT. The following discussion of basic considerations focuses on (a) defining academic learning time and its constituent parts and (b) describing procedures to assess current levels of learning time and identify classroom practices that contribute to ALT. The section on best practices describes strategies for increasing academic learning time that can be offered to classroom teachers through collaboration, consultation, or inservice training by school psychologists.

BASIC CONSIDERATIONS

As instructional consultants, school psychologists can play an important role in helping teachers modify their classroom practices to maximize academic learning time for students. Best practices for increasing academic learning time are based on two preliminary considerations: (a) an understanding of the components of ALT and (b) assessment of classroom time usage and identification of areas in need of change.

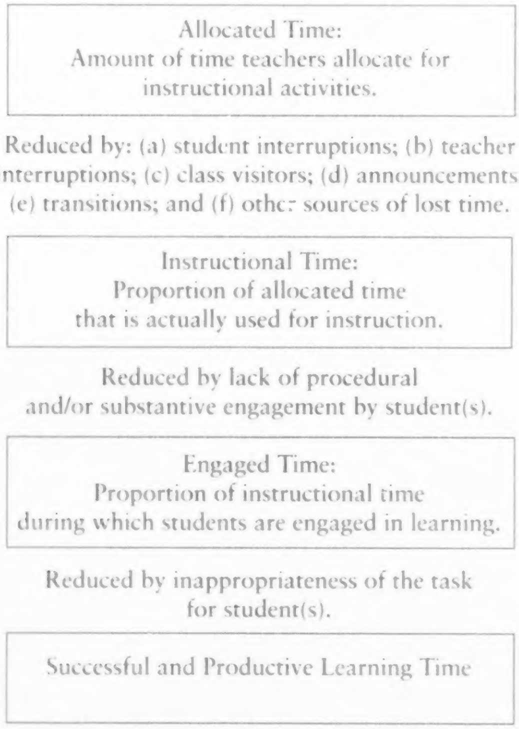
Components of Academic Learning Time

ALT may be defined as the portion of instructional time allocated to a content area during which students are actively and productively engaged in learning (Gettinger, 1995). Four variables contribute to ALT: (a) allocated time, (b) time that is actually used for instruction, (c) engaged time, and (d) academic success and productivity. As Figure 1 illustrates, the process by which allocated time is converted to productive learning time depends on school procedures, classroom practices, and individual differences among students.

Allocated time is the amount of time teachers plan to use or allocate for instructional activities. Allocated time represents the upper limit of in-class opportunities for students to be engaged in learning. Research has documented significant variation across schools and classrooms in the amount of time allocated for instruction (Anderson & Walberg, 1993). Although this chapter focuses on time allocated for instruction *within school*, it is important to note that students in the same classroom self-allocate variable time for learning *outside of school*. For example, one student may self-allocate 20 minutes every day to study spelling words, whereas another may spend only 5 minutes. Over a 5-day period, this results in variable study time across students, ranging from 25 to 100 minutes. Thus, the amount of total allocated time will vary considerably across individual learners, even in the same classroom. Differences in allocated time alone, however, account for a only small portion of the variance in obtained achievement (Gettinger, 1989). Some students simply require more time for mastering content than others. A discrepancy between the amount of time allocated and amount of time needed for learning contributes to low achievement, not allocated time in itself (Gettinger, 1991). As such, the most critical time-allocation issue facing teachers is the need to evaluate and accommodate individual differences among students in the amount of time they require for learning.

Instructional time is the proportion of allocated time that is actually spent on instructional activities.

Figure 1. Components of academic learning time



Allocated Time:
Amount of time teachers allocate for instructional activities.
Reduced by: (a) student interruptions; (b) teacher interruptions; (c) class visitors; (d) announcements; (e) transitions; and (f) other sources of lost time.
Instructional Time:
Proportion of allocated time that is actually used for instruction.
Reduced by lack of procedural and/or substantive engagement by student(s).
Engaged Time:
Proportion of instructional time during which students are engaged in learning.
Reduced by inappropriateness of the task for student(s).
Successful and Productive Learning Time

Studies of time use in schools consistently document that a limited portion of allocated time, between 50 and 60%, is used for instruction (Hollowood et al., 1995). A variety of events typically occur in classrooms that may reduce the number of scheduled minutes that are converted to instructional time. "Lost time" is the amount of time allocated to instructional activities that, for a number of different reasons, is not used toward the completion of those activities. Based on direct observations conducted in eight elementary classrooms, Hollowood et al. (1995) identified six categories of sources of lost instructional time: (a) student interruptions (e.g., disruptive behavior, leaving the room, changing seats, peer conflicts); (b) teacher interruptions (e.g., disciplinary actions, collecting or distributing materials, calling the office); (c) visitors to the class; (d) loudspeaker announcements; (e) transitions; and (f) other sources (e.g., late starts, early dismissals, fire drills).

Engagement rate is the proportion of instructional time during which students are engaged in learning, as evidenced by paying attention, completing written work, or interacting with peers about assigned work. Engaged time includes passive responding, in which students are passively attending to a presentation or task, as well as active responding, in which students are actively responding in a relevant manner to a presentation or task. Even in classrooms where students have an equal opportunity to learn, disparities exist among students in their individual levels of engagement. For example, Wharton-McDonald, Pressley, and Hampston (1998) conducted observations in nine first-grade classrooms of teachers who had been nominated as outstanding in terms of their literacy instruction. Although most students were engaged approximately 80–90% of the time, in some classes, engagement rates were as low as 50%.

Engagement rate is an important time variable; however, it does not impute any particular value to the activities in which students are engaged. The literature has contrasted two distinct forms of student engagement, *procedural engagement* and *substantive engagement* (Nystrand & Gamaron, 1991). Procedural engagement includes observable behaviors, such as paying attention in class and completing assignments. When researchers refer to "engagement rate," they typically mean procedural engagement. Substantive engagement, however, transcends procedural engagement and involves a sustained personal commitment to and engagement in the content of instruction. Although procedural engagement is linked with achievement, academic learning is not possible without sustained, substantive engagement. This distinction between procedural and substantive engagement is important for understanding ALT. ALT depends not only on students' procedural involvement with their schoolwork but also on the nature and quality of schoolwork in which they invest themselves. If students are required to engage in tasks that are not well-matched to their individual characteristics, such as interest, ability level, or background knowledge, then ALT is minimized because substantive engagement is likely to be low. For example, it is possible for students to spend time procedurally engaged in learning activities that are too easy, difficult, uninteresting, or superficial to be of educational value. Therefore, academic success and productivity comprise the fourth important element of ALT.

The *rate of academic success and productivity* reflects the proportion of engaged learning time during which students are performing meaningful and relevant instructional tasks that provide a balance of high and medium success, with more activities targeted at a high-success level. Notwithstanding the need to provide a certain amount of challenging material, research indicates that children gain most from their learning time when they experience a relatively high level of success, about 80% accuracy (Greenwood, Terry, Marquis, & Walker, 1994). That is, students should encounter a preponderance of success in their daily work (e.g., responding to teachers' questions, completing math problems, or practicing spelling words), with the ratio between correct and incorrect responding favoring success by a 4-to-1 margin. Maximizing academic success and productivity depends, to a great extent, on teachers' ability to match learning tasks to individual learner needs in terms of knowledge, skills, and interests.

Although the amount of time teachers allocate (allocated time) and use for instruction (instructional time), as well as the proportion of time during which students are engaged (engagement rate), are all positively correlated with learning, it is the proportion of engaged time that is productive, active and successful that relates most strongly to achievement. In view of the complexity of ALT as depicted in Figure 1, successful efforts to increase ALT are multi-faceted. Specifically, best practices require that (a) teachers maximize their allocations of instructional time and minimize lost time; (b) students maintain high engagement rates, both procedurally and substantively; and, (c) students experience a high level of success on meaningful academic tasks.

Assessment of Classroom Time Usage

The second consideration for school psychologists is familiarity with assessment strategies for evaluating the use of time in classrooms. Best practices for increasing ALT begin with a comprehensive analysis of ALT using the framework in Figure 1. To increase ALT, it is necessary to analyze the constituent parts and then evaluate how time is used or lost within each component. Pursuant to this goal, three assessment strategies are reviewed: (a) self-analysis of time use within an action-research paradigm, (b) ecobehavioral assessment by an external consultant, and (c) functional assessment through collaboration between teachers and consultants.

SELF-ANALYSIS OF TIME USE

The first strategy entails helping teachers analyze their own use of instructional time and target potential areas for change. An action-research approach helps teachers address self-determined issues in their own classrooms, such as the need to increase ALT. It permits ongoing opportunities for teachers to collect data about their own classrooms to guide instructional decisions. When teachers gather data themselves, in the context of their own classroom and focusing on meaningful issues, they are more likely to apply what they learn to their classroom practices (Whyte, 1991).

By using the framework in Figure 1, two types of self-analysis procedures can be conducted to heighten teachers' awareness of their use of instructional time and identify how potential learning time may be lost during the day. The first approach is group-based. In this approach, the school psychologist facilitates discussions among small groups of teachers. Collaboratively, teachers work through the framework in Figure 1, using their knowledge about school operations and estimates of how they allocate class time. Prior to group meetings, teachers are encouraged to maintain personal logs of time usage during a typical one- or two-week period. As a group, teachers begin by placing the number of minutes available in a school day in the top box. Then, they examine common ways that potential instructional time is lost (e.g., recess, transitions, early dismissals). When lost time is subtracted from allocated time, the amount that remains represents available instructional time, and is recorded in the second box. Next, teachers estimate and compare engagement rates in their classrooms across different instructional formats (teacher-led discussion, independent seatwork, etc.), academic domains, and learning tasks to record in the third box. Finally, teachers attempt to construct a profile of overall success among students in their classrooms (e.g., high-, average-, or low-success students) to estimate the proportion of learners for whom ALT is further reduced because the work is too difficult. This mutual analysis of time usage among teachers in small groups provides a forum for collective dialogue on ways of modifying classroom practices to increase ALT. A key feature of action research is the provision of structured opportunities for discussion and sharing of strategies.

The second procedure entails a more extensive, focused analysis of time use within an individual classroom, typically conducted in consultation with a school psychologist. As with the group approach, this analysis relies on the framework in Figure 1. Assessment involves the use of self-monitoring procedures to measure actual time usage in classrooms or for individual students. For example, Paine, Radicchi, Rosellini, Deutchman, and Darch (1983) developed a structured schedule analysis form and step-by-step procedure to help teachers examine how they are using instructional time. For this procedure, teachers construct a written schedule of all classroom activities and compute the percentages of available time they devote to each activity. Activities are then ranked from highest to lowest based on the percentage of time allocated to each one. It is also useful for teachers to rate student achievement and overall student engagement in each curricular area on their schedule. This allows them to determine whether there is a relationship between overall achievement and allocated time and, in turn, whether allocated time reflects the needs of students. For example, if spelling performance is lower than expected or desired, teachers can examine instructional time in spelling relative to other content areas and determine whether the time matches students' learning needs.

Perhaps the most important aspect of self-analysis procedures is when teachers, either in groups or individually, reflect on the extent to which their classrooms are characterized by high or low levels of ALT, and think about what may be facilitating or impeding the accumulation of ALT. In some cases, teachers may conduct a small-scale study in their classroom over a short period to systematically evaluate the effect of an instructional change on students' ALT (e.g., replacing individual oral reading with choral responding for one to two reading lessons and, then, comparing engagement rates). To guide their thinking and encourage reflective practice, teachers may also be directed to respond to specific probes, such as those proposed by Paine et al. (1983). For example, teachers might ask themselves: (a) Do I provide students with frequent opportunities to respond? (b) Does the time I allocate to activities match students' needs? (c) Am I successfully managing transition times? (d) Have I ensured that all students work on materials that are appropriate for their skill level? (e) Does my schedule minimize organizational time?

ECOBEHAVIORAL ASSESSMENT

The second assessment approach, which relies on consultants or classroom observers, is to collect data on classroom variables, engagement rates, and success levels among students through systematic, direct observation. One observational method for studying academic engagement within the context of classroom and teacher variables is *ecobehavioral assessment* (Greenwood, Carta, & Atwater, 1991). The primary focus of ecobehavioral assessment is on active student responding. This approach is used to identify naturally occurring variables that are associated with high versus low levels of engaged behaviors. Although student engagement is not a direct measure of learning, it is positively correlated with achievement for students, both with and without disabilities. The goal of ecobehavioral assessment is to observe student engagement, a proxy for learning, over multiple activities, instructional arrangements, and teacher behaviors to arrive at an understanding of variables that are associated with high engagement. Although a number of different procedures may be used to complete an ecobehavioral assessment, the most frequently used systems are based on the *Code for Instructional Structure and Student Academic Response* (CISSAR) (Stanley & Greenwood, 1981). Classroom observers, using the CISSAR, collect data on the classroom context (e.g., activity, materials, instructional grouping), teacher variables (e.g., behavior, instructional focus), and academic responding among students. Unlike the self-analysis methods described, direct observation approaches employ complex codes that have the disadvantage of requiring independent classroom observers, but have the advantage of offering detailed information about classrooms, teacher behaviors, and student responding.

FUNCTIONAL ASSESSMENT

The third procedure for evaluating classroom time usage is functional assessment. Functional assessment is a direct method for examining relations between classroom performance and features of the instructional environment. A functional-assessment approach relies on collaboration between teachers and school psychologists, and involves three phases: (a) observing and describing the educational environment (e.g., task, materials, instruction, organization, etc.) during periods of high and low ALT; (b) generating hypotheses about the relation between ALT and the instructional context; and (c) testing hypotheses using experimental functional analysis, or a systematic manipulation of variables that contribute to ALT (Daly, Witt, Martens, & Dool, 1997).

A functional-assessment approach may be used to examine ALT for an entire class or an individual student. To implement functional assessment, the teacher or school psychologist conducts observations during instructional periods when academic performance and student engagement are low, as well as during periods when performance and engagement are high. Based on collective observations, teachers and consultants develop hypotheses about the sources of high versus low ALT and, based on these hypotheses, make modifications in the classroom structure or delivery of instruction to maximize ALT. To illustrate this procedure with an example: A teacher noted that students were struggling with science. The school psychologist observed during two to three science periods. Students spent approximately 40% of the instructional period moving between the front of the classroom, where directions for the science activity were written on the board, to the back of the room, where science materials were located, and then to their seats, where they were expected to write in their science journals. The school psychologist also noted a high level of off-task behavior during the time that students were making these transitions. Based on additional observations during more productive instructional periods, the psychologist and classroom teacher developed the hypothesis that low ALT was linked to the organization and location of critical components for science activities (directions, materials, and journals). To test this hypothesis, prior to the next science lesson, the teacher printed directions for the activity on a page and separated materials (i.e., different types of rocks) into individual bags for students to keep at their desks. The teacher and school psychologist, then, monitored student engagement during the science period as well as learning outcomes (e.g., quantity and quality of journal entries; accuracy of student responding to teacher questions). Both performance and engagement improved when these modifications in the structure of the science lesson were implemented. In sum, school psychologists can initiate teachers' thinking about instructional time through an analysis of the four components that comprise ALT by using the framework in Figure 1. Working from evaluations of current time use, based on self-analysis, classrooms observations, or functional assessment, school psychologists are in a position to provide individual consultation or inservice training to assist teachers in increasing students' ALT.

BEST PRACTICES

Research on the relationship between learning time and achievement supports the recommendation that teachers should be encouraged to incorporate teaching methods and classroom practices that maximize ALT. Using assessment information (e.g., classroom time-use logs, observational data), school psychologists can provide individual consultation or direct training to assist teachers in increasing ALT. Strategies for increasing student learning time have been derived from over 25 years of research on effective teaching. Because increases in student engagement covary with gains on both Curriculum-Based Measures and standardized tests, effective-teaching research has used ALT as an outcome variable to determine the effectiveness of instructional practices.

Effective-teaching research may be organized into three broad categories depending on the research paradigm. These include (a) a process-product paradigm, which examines the relationship between teacher behavior and student engagement; (b) a classroom-ecology paradigm, which considers the structural and organizational features of classrooms that are associated with student engagement and learning; and (c) a mediating-process paradigm, which focuses on cognitive-behavioral activities that mediate the relationship between teacher behavior or classroom structure and student engagement. All three strands of instructional research have contributed to our understanding of the teaching-learning process and to knowledge of best practices for increasing ALT (Gettinger & Stoiber, 1999). Consistent with these paradigms, best practices for increasing ALT are discussed in terms of three types of recommendations, as shown in Figure 2. Best practices address: (a) teacher behaviors, (b) structural arrangement of classroom environments and learning situations, and (c) student-mediated strategies.

The following sections describe practices that are intended to serve as guidelines for school psychologists in their role as classroom consultants. Not every procedure may be effective or efficient for all classrooms and teachers. Because of individual teaching styles and classroom arrangements, school psychologists must work collaboratively with teachers to analyze time use, target areas in which learning time can be increased, identify students whose ALT is below average, and develop strategies that are tailored to teachers' individual styles and individual learners' needs. A critical role for school psychologists is to facilitate teachers' utilization and, when necessary, modification of these procedures in their classrooms. Teachers should always be encouraged to modify methods based on their own experiences. Furthermore, teachers constantly need to monitor their own behavior and its relationship to students' performance to refine, personalize, and develop methods that are maximally effective in increasing ALT.

Process-Product Research Paradigm: Interactive Teaching Behaviors

Teacher behaviors and instructional management strategies have an impact on student behavior so as to promote ALT. Collectively, these behaviors reflect what has been termed a directive or *interactive teaching style*. Interactive teaching encompasses multiple teaching behaviors that are associated with high levels of ALT. (See Figure 2.)

Figure 2. Best practices for increasing academic learning time within three research paradigms

Process-Product Research Paradigm:
Interactive Teaching Behaviors

Academic focus
Interactive instructional activities
Active academic responding
Teacher-selected activities
Student-teacher interactions
Delivery of instruction
Classroom management strategies
Proactive planning

Classroom-Ecology Research Paradigm:
Structure of Learning Activities

Adaptive instruction
Integrated curriculum approach
Flexible grouping practices
Physical arrangement of classrooms

Mediating-Process Paradigm:
Student-Mediated Strategies

Cognitive strategies
Self-monitoring
Self-management

The primary characteristic of interactive teaching is a strong *academic focus*. Academic focus is reflected in the amount of time devoted to academic versus nonacademic activities and in the type of instructional interaction that prevails in the classroom. According to Good and Brophy (1996), classrooms with a strong academic focus share the following characteristics: (a) systematic, teacher-structured activities; (b) lessons and content related to attaining specific goals; (c) rapid pacing of lessons; (d) ready availability of teaching materials; (e) high levels of student participation and responding; (f) student accountability for homework; and (g) frequent monitoring of students' performance through weekly and monthly tests.

The nature of teaching activities is also related to ALT. Not all academic activities are of equal instructional value. *Interactive activities*, such as discussion, review, or reading aloud, are more strongly related to ALT than non-interactive activities, such as silent reading or completing independent seatwork. Spending more time in interactive instructional activities may be initiated after teachers analyze their classroom activities and consider ways to modify activities to be more interactive. For example, math problems might be solved collectively by small groups of students rather than individually as an independent seatwork assignment.

Another important aspect of interactive teaching is the nature of children's participation in learning activities. *Active academic responding* by students is related to high levels of ALT. Active responding involves children's practicing academic tasks, such as answering a question, reading a text, or performing the steps in solving a problem. Incorporating some element of active student responding into every learning activity and encouraging responses from all students during group lessons and discussion can increase ALT.

Again, a careful analysis of classroom tasks might reveal how active responding can be built into activities. For example, students could be encouraged to ask questions and respond to answers from peers as well as answer their classmates' questions, rather than having the teacher do so. Beyond fostering active participation, this strategy allows students to practice good listening skills. Furthermore, active responding affords the teacher numerous opportunities to monitor students' progress and provide corrective feedback about their performance.

Interactive teaching involves a high level of *student-teacher interaction*, which is also associated with high levels of ALT. As the teacher interacts with and directs questions to students, it is important that all children be given an opportunity to participate, not just those who are eager to respond. Low-functioning students, for example, may accrue lower amounts of ALT because of fewer student-teacher interactions and fewer opportunities to respond.

Many teachers state that maintaining interaction and engagement among all students during whole-class discussions is one of the most difficult aspects of interactive teaching. An effective questioning technique to maintain engagement is to direct questions to students randomly or in ordered turns, moving in sequence among all children in the class. Reshuffling and cycling through a set of index cards with students' names ensures that students are called on during question-and-answer periods. Random selection in calling on students has the effect of keeping students attentive, particularly if the teacher occasionally returns to a student who has recently answered a question.

Another recommendation for maintaining engagement during student-teacher interactions is to wait at least 5 seconds before providing a correct answer to a question or calling on another student to respond. To make teachers aware of "wait time," school psychologists should ask teachers to consider a typical question they might pose to students during instruction, then silently count to five to experience a 5-second wait. If teachers want to maintain students' engagement and increase willingness and ability to answer questions, then the teacher must provide all students adequate time to answer. When teachers fail to provide sufficient time for responding, students learn they can remain uninvolved simply by failing to respond immediately. Another aspect of student-teacher interaction is feedback. Children perform better and maintain high levels of ALT when they receive frequent performance feedback. Feedback that is characterized by specificity and academic relevance maximizes ALT. Information given to students about their performance should indicate whether responses are correct or incorrect, and provide specific suggestions for rethinking or redoing the work.

A number of procedures related to the actual *delivery of instruction* within an interactive teaching approach also influence ALT among students. For example, instructional time is lost in classrooms when teachers have difficulty obtaining students' attention and getting started on lessons, or making smooth transitions between activities. Several strategies can reduce the amount of time needed to start new activities. One strategy is to select a discriminative stimulus or cue that foreshadows a transition to a new activity. The phrase or cue can be thematic, may vary every month, and can be selected by the students themselves. In one third-grade classroom, a teacher used concepts from a science unit on sea animals and plants to cue classroom instructional transitions. For example, she used the cue, "Time to go deep-sea fishing," to signal that the class was ready for independent seatwork, and the cue, "Time to surface," to direct children to conclude their independent work and come to the rug for whole-class discussion. Teachers should record the time it takes students to pay attention following the cue and to monitor the reduction in the amount of time needed across weeks. Children can be challenged to reduce the time it takes the class to get ready for a lesson from the previous time. Another guideline is to wait to begin instruction until everyone is paying attention to prevent having to repeat content or directions for completing work. The amount of time targeted for students to "get ready" should be optimal, allowing slower students sufficient time to attend while maintaining readiness among the faster ones.

Another recommendation related to the delivery of instruction is to stimulate interest in new content by relating it to a previous lesson or experience, or starting with a motivating activity to make the initial contact with the lesson positive. Students' engagement in tasks can be heightened by indicating why the material is being learned and by suggesting ways in which the new learning may be related to other events or experiences in their lives.

769

Classroom management strategies designed to conserve instructional time is another component of interactive teaching. The best management strategy for non-instructional transitions is to instill awareness in students of classroom rules and procedures for such activities. Teachers with well-managed classrooms invest considerable time, particularly early in the year, teaching students the routines necessary for smooth classroom operation.

Finally, interactive teaching includes *proactive planning*. Proactive planning includes all steps a teacher takes to be prepared to deliver a lesson. The first step is to develop clear goals and objectives for instruction; that is, what students are expected or desired to learn. Once goals and objectives are established, the method of instruction must be determined (e.g., large-group versus small-group, teacher-directed versus student-directed). After deciding what to teach and how to teach it, the next step is to communicate goals and expectations to students. Effective communication includes giving precise instructions that clearly describe the goals of the lesson, activities to be completed by students relative to their goals, and evaluation procedures.

A significant amount of lost time often results when students do not understand how they are to proceed with assigned tasks. To ensure that students understand instructions, teachers can ask students to paraphrase the directions and self-identify problems that might occur in understanding or following directions. In addition, whenever possible, directions should be written and placed where they can be seen and referred to by students as needed. It may also be necessary to distribute outlines, definitions, or study guides to help students organize their thoughts and focus their attention on lessons or assigned work. Before presenting a lesson, teachers can also brainstorm potential problems that could result in loss of ALT. Problems might be academic (What will I do if students have trouble understanding a concept?), behavioral (What will I do if students are off task?), or administrative (What will I do if some students do not have their materials?). Once trouble spots are identified, the teacher can then generate workable solutions. The more prepared a teacher is to address problems, the more time available for students to be actively engaged in learning.

In summary, interactive teaching occurs when the teacher assumes a central, active, and directive role in the instructional process. Teachers who emphasize academic goals and display high levels of involvement with students on learning tasks generate high levels of ALT. The teacher selects the academic activities and leads students through academic tasks to accomplish goals and objectives. There is a high level of student-teacher interaction, most of which is initiated by the teacher. The majority of instructional time is devoted to the teacher's presentation, explanation, and demonstration. Practice, feedback, questioning, and review of activities also figure prominently in daily instruction. The teacher monitors student progress and provides corrective feedback. The teacher holds and conveys high expectations for student performance and provides students with many opportunities to experience success. Finally, planfulness, clarity of directions, praise, and feedback are all associated with high levels of ALT.

Classroom-Ecology Research Paradigm: Structure of Classrooms and Learning Situations

Increasing ALT also requires restructuring and reorganizing classrooms that extend beyond individual teacher behaviors. Several approaches have been shown to promote high levels of ALT and achievement among diverse students. Collectively, these strategies are called *adaptive instruction*. Adaptive classrooms are designed to accommodate a wide range of individual differences among students. Conceptually, adaptive instruction is a two-way enterprise between the classroom environment and the students. Efforts to adapt to student diversity have a dual focus: (a) structure the learning environment to accommodate students' needs and (b) provide students with independent learning strategies to improve their capability to adapt to the demands of the classroom. Three adaptive strategies for restructuring classroom learning are described: (a) integrated curriculum, (b) flexible grouping, and (c) physical arrangement of classrooms.

The recommendation for an *integrated curriculum strategy* emerges from the lack of adequate time for content-area teaching that often occurs, particularly in the upper elementary grades. Lack of instructional time is a limitation to improving the quality of instruction in areas such as science and social studies. For example, with restricted instructional time, many elementary science programs include only assigned reading activities in science textbooks. Educators attribute negative attitudes displayed by students at the secondary level toward content areas, such as science and history, to lack of in-depth instruction in elementary school that includes hands-on activities. At the same time, educators stress the importance of content-based reading activities as vehicles for developing applied reading comprehension and thinking skills, but they also acknowledge the limited amount of instructional time available for such activities.

An integrated curriculum strategy that teaches applied reading skills across a range of content areas is one approach to circumvent this problem; that is, to increase ALT in content-area reading while providing sufficient time for in-depth thinking activities. The goal is to improve the quality of both content-area and reading instruction within an integrated time frame that reallocates the combined instructional time assigned to all curriculum areas. For example, Romance and Vitale (1992) described an integrated curriculum strategy designed to increase the time allocated for in-depth science teaching by replacing the district-adopted basal reading program with science-content-based instruction that concomitantly facilitated reading comprehension skills. They found that ALT in both science and reading activities increased for students as did achievement, attitudes toward science and reading, and academic self-confidence.

Flexible grouping practices also allow teachers to maximize ALT for all students. Whole-class instruction has the potential for enhancing engagement because the teacher is able to monitor and foster active responding among all students at one time. Whole-class instruction, however, may not provide individual students with sufficient opportunities to respond, or with material at an appropriate level of difficulty to ensure a high success rate necessary for ALT. Individual seatwork, on the other hand, lends itself to providing high levels of student success, but it may minimize students' engagement. Furthermore, individual teaching and learning activities do not always represent the most efficient use of allocated instructional time. Teaching students in small groups or having students work cooperatively in groups can circumvent some of the problems inherent in individual or whole-class teaching.

The key to grouping practices that are successful in increasing ALT is flexibility. Membership in groups should change on the basis of specific needs of students and the nature of the learning activity. Decisions about grouping for instruction are important because of the management implications and instructional impact. For example, heterogeneous grouping arrangements foster high levels of engagement in activities that are designed to be cooperative; that is, activities in which students coordinate their individual skills and efforts to achieve a group goal. Typically, exploratory tasks lend themselves to heterogeneous grouping. These tasks are designed to foster social development and enrich or apply basic skills, such as playing games or solving problems. For group activities to maintain a high level of student involvement, tasks must be selected to allow each student to function as a contributing member. Every student needs the opportunity to be both challenged and successful on the learning task, which may require adding easier or smaller components for low-ability students as well as adding more difficult or complex ones for high-ability students. Homogeneous grouping, on the other hand, allows students to work on material according to their achievement level and pace. Homogeneous grouping arrangements allow the teacher to provide assistance geared to the level of students in the group, thus maximizing their ALT. Prescriptive tasks are more appropriate for homogeneous groups, such as completing independent seat work problems, receiving teacher-directed explanations, or being tutored in basic skills.

Another grouping practice that results in high levels of ALT is peer tutoring. In this grouping structure students take turns serving as tutors (who evaluate and provide feedback about responses) or tutees (who respond to academic prompts). An effective method of class-wide peer tutoring has been developed by Greenwood, Delquadri, and Carta (1997). This method involves pairing students for reciprocal tutoring, changing partners regularly, providing immediate feedback and correction of errors, and using team reinforcement contingent upon performance. When students are engaged in peer tutoring, half the class provides an answer while the other half evaluates the answer, keeping all students consistently engaged in the task. To implement an effective peer tutoring program, teachers must carefully select instructional content, provide students with clear instructions, and monitor student understanding. When implemented correctly, peer tutoring increases student engagement across academic subjects, providing benefits to tutors and tutees (Skinner, Shapiro, Turco, Cole, & Brown, 1992).

In sum, grouping children to maximize ALT, particularly children with academic problems, should reflect teachers' knowledge of engagement patterns in their classrooms and how to make the best use of instructional time. Each grouping option impacts differently on students' engagement. Whole-group instruction may be easiest to manage because the teacher can supervise all students at one time. Small-group instruction and peer tutoring entail greater planning and management skills, but they are more effective in engendering high levels of interaction. Finally, individualized instruction facilitates matching instruction to each child's needs and skill level to maximize success rate. Efforts to increase ALT reside in the application of grouping practices according to the particular needs of students.

The third structural approach to increase ALT relates to the *physical arrangement* of the classroom. Classrooms should be arranged in a way that matches the typical grouping practices and instructional method. For example, if a teacher regularly engages in whole-class instruction, then arranging desks in groups so that some students must turn around in their seats to see the board is not the best arrangement. Another consideration when arranging a classroom is the flow of traffic within the room. To provide students with prompt feedback and minimize disruptions teachers must have easy access to all areas of the classroom. A well-organized classroom allows a teacher to monitor all students from anywhere in the room and has direct routes across the classroom so teachers can quickly redirect students who are off-task. When examining the flow of traffic, placement of both high traffic and quiet areas is important. High traffic areas, such as supply shelves or pencil sharpeners, should be placed away from student work areas. Time-out or quiet areas should be separate from the group, but not completely isolated. It is important for teachers to be able to monitor students in these areas while continuing to work with other students in the classroom. Physical arrangement of the classroom can reduce the amount of ALT lost to disruptions and off-task behavior.

Mediating-Process Paradigm: Student-Mediated Strategies

Whereas best practices for increasing ALT based on the process-product and classroom-ecology paradigms emphasize instructional and managerial strategies external to the learner, the mediating-process paradigm focuses on within-learner or cognitive variables that maximize ALT. Consistent with Carroll's model, research has shown that student learning is a function of the discrepancy between the amount of time available for learning and the time students actually spend engaged with the content of instructional activities (Gettinger, 1989). Even when teachers consistently implement best practices for maximizing ALT, students may spend less time than needed or less time than what is available because of low motivation, low self-efficacy, or lack of self-monitoring skills. Furthermore, although students may appear to be actively engaged in learning, their ALT may not be optimal because they employ ineffective learning strategies or may have difficulty allocating attention efficiently to information within tasks. Therefore, best practices for increasing ALT include not only procedures to improve how teachers allocate and structure available time (instructional efficiency) but also methods that focus on how students use instructional time (cognitive efficiency).

According to the mediating-process perspective, time use is linked to students' use of strategies for planning and organizing their learning time and monitoring cognitive engagement. Cognitive engagement requires some degree of self-regulation of learning and performance among students (Zimmerman, Greenberg, & Weinstein, 1994). To maximize cognitive engagement, students may require training in learning strategies, self-monitoring skills, and self-management behaviors. Unlike best practices that emphasize teaching practices or classroom organization, these student-mediated procedures involve individual students in the regulation of their own ALT. This mediating-process research paradigm emphasizes cognitions as mediators of ALT. Best practices evolving from this paradigm focus on how to develop the metacognitive skills students need to regulate their ALT effectively rather than relying on conditions of the environment of instruction to produce ALT. Within this paradigm, there are specific strategies designed to help students control their own ALT.

The first component of a student-mediated approach for maximizing ALT is students' *acquisition and use of strategies* for using study time efficiently and managing time effectively. According to Pressley and his associates, effective strategy instruction involves four elements: (a) providing students with knowledge about strategies to promote cognitive engagement during learning tasks and how to use them, (b) demonstrating how and when utilization of strategies is appropriate for maximizing the efficiency of learning time, (c) providing feedback on the appropriate use of strategies, and (d) providing instruction concerning when and why strategies should be used and how strategy use can enhance their learning time (Pressley et al., 1995). The systematic application of strategy training as part of classroom instruction can increase ALT. If students are taught to approach learning tasks in a structured, organized fashion, then they will be more efficient with their learning time. By facilitating students' ability to organize information more efficiently, strategy training also increases the probability of correct responding and active engagement during learning activities. For example, the use of strategies, such as story-mapping or question-generation, during individual reading periods enhances learning and retention of material because students are cognitively engaged and actively interacting with the text while they read (Wood, Woloshyn, & Willoughby, 1995). Similarly, performance improves when students are taught to use a systematic error-correction procedure during the time allocated for individual study of spelling words. Again, it is hypothesized that an error-correction strategy increases active engagement and success during the allocated learning time (Graham, Harris, & Loynachan, 1996). It is widely accepted that active learning strategies increase students' regulation of their own learning and ALT. Although beyond the scope of this chapter, there are several empirically supported approaches to strategic learning (see, for example, Pressley et al., 1995; Wood et al., 1995).

The second component of student-mediated strategies is *self-monitoring*. A key self-regulative variable within the mediating-process paradigm is the quality of students' cognitive monitoring. If students do not realize they are not learning, then they will not plan or adjust their time use appropriately. There is evidence that students may fail to monitor their learning and self-regulate their use of learning time, even when they are motivated to learn or when instruction has been delivered so as to maximize ALT (Stipek, 1998). Research has provided information about ways in which students can be taught to self-monitor their learning time more effectively and, in turn, maximize their ALT. These procedures directly involve students in regulating their own ALT and focus on active thought processes that enhance learning.

One example of self-monitoring is the use of self-correcting techniques. Several types of self-correcting materials have been shown to be effective, including flash cards, answer tapes, overlays, or checking stations. Another method to help children monitor their own learning time is to have them keep a personal log of time use, including the duration of study time, frequency of engaged behaviors (e.g., answering questions, writing responses), task completion, or overall level of performance. Kern, Dunlap, Childs, and Clarke (1994), for example, increased engagement by having children record on sheets placed in the corner of their desks whether they were or were not "on task" at signaled intervals. Methods as simple as touching a child on a shoulder can also be used as cues. Self-recording has been found to significantly influence children's behavior, including their levels of ALT.

A third component of student-mediated methods for increasing ALT is *self-management*. If given proper training and supervision, then students are capable of assuming a high degree of autonomy through the use of self-management procedures. Furthermore, self-management techniques result in increased learning and ALT (Shapiro & Cole, 1994). Self-management strategies contribute to students' independent functioning in the classroom. To manage the range of ability levels among diverse learners and enable each child to accrue maximum ALT, a systematic approach for the development of independent learners is often necessary. For example, even young children can be taught directly to guide themselves through much of their day with minimal assistance from a teacher and with minimal loss of engaged learning time (Jones & Jones, 1998). There are several best practices for teaching students to become independent learners. For example, teaching students a systematic task approach can be accomplished by using a step-by-step sequence that helps children structure their learning behavior. This may consist of having students ask themselves a series of questions listed on individualized job cards (e.g., What materials do I need? How much time do I have?). Before beginning a task, students use their job cards to determine what needs to be done and whether they have the knowledge, skills, materials, and time to complete it. Overall, self-management enables students to take an active role in managing and maximizing their own learning time.

SUMMARY

Academic learning time is one of the most important correlates of achievement, and its linkage with learning is one of the most consistent findings in educational research. During the past 25 years, much has been learned about maximizing the amount of academic learning time that students experience. This continuing focus on learning time has important implications for school psychologists. First, it is incumbent on psychologists to ensure that classroom teachers have an awareness of the importance of ALT and its relationship to student achievement. Second, school psychologists can facilitate classroom-based or school-wide assessment of time use, as well as the identification of areas to target for improvement in order to maximize learning time. Finally, through consultation, collaboration, or inservice training, school psychologists may help teachers acquire and implement more effective classroom practices to increase students' ALT. Assisting teachers and schools to manage instructional time effectively is important to increasing ALT and improving academic performance for all students.

ANNOTATED BIBLIOGRAPHY

Algozzine, B., Ysseldyke, J., & Elliott, J. (1998). *Strategies and tactics for effective instruction.* Longmont, CO: Sopris West.

This book divides instruction into four parts: planning, managing, delivering, and evaluating. Within each area the authors provide easy-to-use, research-based approaches for improving instruction and increasing learning time for students.

Anderson, L. W., & Walberg, H. J. (Eds.). (1993). *Timepiece: Extending and enhancing learning time.* Reston, VA: National Association of Secondary School Principals.

In this brief, edited volume, the authors, all experts on educational time use, have written succinct chapters that explain how educators can extend and enhance learning time both within and outside of school. In the final chapter, written by the editors, major issues are summarized, and a table presents a series of excellent recommendations derived from common themes across all chapters.

Goodman, L. (1990). *Time and learning in the special education classroom.* Albany, NY: State University of New York Press.

The purpose of this book is to help teachers of students with special education needs to examine their own teaching to look for ways to improve effectiveness and learning time. In addition to reviewing research related to time and learning, the author provides many practical applications of findings, including strategies for conserving instructional time and enhancing academic learning time among students with learning problems.

Witt, J., LaFleur, L, Naquin, G., & Gilbertson, D. (1999). *Teaching effective classroom routines.* Longmont, CO: Sopris West.

This book provides teachers with step-by-step methods for developing classroom routines. The development of classroom routines can reduce the amount of learning time lost to administrative tasks and disruption. In addition to providing teachers with explicit instructions for developing and maintaining classroom routines, the book contains examples and useful reproducibles.

Best Practices in Preventing Academic Failure and Promoting Alternatives to Retention

Mary Ann Rafoth
Indiana University of Pennsylvania

OVERVIEW

National attention was refocused on the issue of retention of students in grade when President Bill Clinton called for an end to "social promotion" in his 1998 State of the Union address. Logic would appear to dictate that if there is a national call to stop sending students who do not meet specific standards on to the next grade, then there must also be a national mandate to retain those unprepared students at their current grade level. However, both the practices of retention and social promotion have come under increasing fire from researchers, politicians, and educators in recent years. The National Association of School Psychologists (NASP) has found both to be "failed practices."

NASP encourages instead more effective diagnostic assessments and individualized teaching to identify learning problems and more resources to address these problems (National Association of School Psychologists, 1998). NASP argues that the cost of effective prevention and remediation are far less than the estimated $6,000 a year cost per child of retention or the cost of socially promoting a child without needed skills. Nevertheless, effective interventions before students experience serious failure in the classroom are more easily talked about than put into place. So, even though there was no suggestion that simply retaining students would be beneficial, many school districts, particularly large urban centers (e.g., New York, Chicago, Detroit, Houston) began to institute policies that were destined to increase the number of students retained dramatically. These changes took place even after a decade of analysis of research and debate had largely concluded that retention was a costly and ineffective intervention.

Now school systems grapple with what to do with large numbers of students who fail to meet standards that were set as benchmarks for promotion to the next grade. Meanwhile, individual teachers and parents continue to struggle with issues of delayed entry and retention such as the following: A preschool teacher tells the parents of a 4-year old boy with a birthday just before the school cutoff date that they may want to have him spend another year in preschool before facing the demands of public kindergarten. It is recommended to parents of a first grader that their daughter be retained in first grade—because she's slow picking up reading and appears younger than her classmates. A teacher recommends that a boy in fifth grade repeat the year because, while he appears bright and capable of doing the work, he has done very little in class and has handed in virtually no homework assignments. A group of eighth-grade teachers draws up a list of students they feel have not mastered the academic skills necessary to proceed to high school. Many of the students have already repeated one year in school; most are boys from lower socioeconomic classes who have been placed in the lower tracks since early in elementary school. A high school sophomore with frequent absences from school is forced to repeat tenth grade because she failed to accumulate sufficient credits to enter the eleventh grade.

Every year, approximately 2.4 million U.S. students are held back in school, many under circumstances similar to those described above. The percentage of students retained has shown a steady increase over the last 25 years (U.S. Department of Commerce, Bureau of the Census, 1966, 1990, cited in Alexander, Entwisle, & Dauber, 1994). Minority youth and boys, especially if they live in poverty and their parents did not finish high school or they lack a college education, are more frequently retained; that is, over half of African-American boys and 49% of Hispanic boys are old for grade by age 14 (Alexander et al., 1994; U.S. Department of Commerce, Bureau of the Census, 1992, cited in Roderick, 1995). Yet, research on the efficacy of retention continues to indicate that this is a failed strategy to remediate academic problems.

Frequently, school psychologists are involved in making individual retention decisions or influencing the policies of their school districts. For the most part, retention is of questionable educational benefit and may have negative effects on achievement, self-concept, school dropout rates, and high-risk behaviors in adolescence. The general public and even many teachers continue to believe in its efficacy, however. Many teachers and school administrators continue to see retention as a positive practice that acts to lessen daily school failure and to motivate students to work harder (Tanner & Combs, 1993; Tomchin and Impara, 1992).

This chapter provides the school psychologist with a brief review of the research on student retention as well as discussion of the main causes of academic failure that lead to retention at different points in a student's school career. The concluding section will address the role school psychologists may play in helping school districts move to systemic approaches to preventing academic failure, avoiding decisions about retention, and alternatives to retention that may better meet the needs of students experiencing failure at school. Of the many professionals involved either in developing district-wide retention policies or in making retention decisions about individual students, the school psychologist is uniquely qualified to act as a consultant in generating alternatives. School psychologists should help to evaluate the reasons for school failure, plan appropriate instructional programs for the following year whether or not the child is retained, and act as consultants both to parents faced with retention decisions and to their school districts in developing programs that are viable alternatives. Best practices regarding non-promotion center on a thorough understanding of the research and careful consideration of the needs of the individual student. Best practices regarding avoiding academic failure center around systemic responses to the main sources of failure for students at key grades: failure to learn to read in the primary grades; inability to organize, study efficiently, and learn independently in middle school; and loss of motivation in high school.

BASIC CONSIDERATIONS

Retention or non-promotion is the practice of requiring a child to repeat a particular grade or requiring a child of appropriate chronological age to delay entry to kindergarten or first grade. With the introduction of graded schools in the nineteenth century, retention emerged as a response to the problem of students unprepared for the academic demands of the next grade. While concern about possible negative effects of retention has been expressed since the 1930s, the practice appears to be on the increase. Little research exists to validate its effectiveness (Holmes & Matthews, 1984; Jimerson, 1999; Jimerson, Carlson, Rotert, Egeland, & Sroufe, 1997; Mantzicopoulos & Morrison, 1992; Medway & Rose, 1986; Reynolds, 1992; Shepard & Smith, 1990). Only one major study, *On the Success of Failure*, by Alexander et al. (1994) appeared to support the use of retention at least in the higher grades. This study suggests little reason for retention upon close examination, however. Only a continuous skill degradation among low-achieving students appears to have been halted by retention, and even this effect may have been an artifact of the research design (Dawson, 1998). Additionally, other research published in the medical literature suggests that adolescents who are old for grade are at much greater risk for a variety of problem behaviors including smoking, chewing tobacco, drinking alcohol, driving with someone who is drinking, using alcohol or other drugs before sexual intercourse, and using drugs (Byrd, Weitzman, & Doniger, 1996). Similarly, in 1997 issues of *Pediatrics* (Byrd, Weitsman, & Auinger, 1997) and the *Journal of the American Medical Association* (Resnick et al., 1997) contained articles that examined students who were old for grade (regardless of reason). Both found that higher rates of behavior problems were reported in this group. The use of statistical techniques such as meta-analysis and causal modeling has helped overcome the weaknesses of individual studies and the use of larger databases have established more definitive relationships between retention and later achievement and social growth. In addition, there appears to be increasingly clear evidence that being old for grade is itself a risk factor.

Kindergarten and Elementary Level

Children are often recommended for retention at the kindergarten level because they have failed to acquire basic readiness skills and are not progressing in reading. Sometimes these determinations are made because of poor performance on a readiness test administered before entry into kindergarten or at the end of the year. Failure to display skills, particularly in reading in the classroom, coupled with low achievement scores is often the reason a child is suggested as a candidate for retention after completing a year of kindergarten or first grade. Some children enter kindergarten with little exposure to academics, the school routine, or prerequisite skills such as letter and number recognition, which are typically taught in most preschools. Children from home backgrounds in which such exposure is limited may find themselves candidates for delayed entry into kindergarten or retention. Again, most likely to be retained in kindergarten are African-American or Hispanic boys who are chronologically young for grade, developmentally delayed, and living in poverty. On the other hand, children who attend Headstart are less likely to be retained (National Household Education Survey, cited in Zill, Loomis, & West, 1997).

Delayed entry or retention at the kindergarten level also occurs because some children are judged to be "developmentally immature." These children seem to be slightly delayed in social, motor, and/or readiness skills and in need of a year to grow or mature neurologically and thereby catch up with their peers. Likewise, children who are physically small or relatively young compared with their peers (because of cutoff dates for school entry) are often candidates for delayed entry or retention. Many parents and teachers believe that the extra year will allow the child, especially if the child is a boy, to compete more effectively with peers the following year (Mergendollar, Bellismo, & Horan, 1990). However, Laidig (1991) found that delayed entrants to kindergarten, when compared to children who started school on time, had significantly lower scores on standardized achievement tests in senior high school with ability controlled for in the analysis. Delayed entry has also been associated with a higher rate of involvement in high-risk behaviors in adolescence.

While late-birthdate children who are retained or held out of school for a year initially may do better than those enrolled in first grade at the prescribed age, longitudinal studies show that initial achievement gains do not hold up over time or remain very slight (Cameron & Wilson, 1990; Crosser, 1991; Kundert, May, & Brent, 1995). For instance, Miller and Norris (1967) divided first graders into three groups based on age at school entrance. They found significant differences between young, middle, and old first graders on three of six readiness measures. At the end of 4 years, however, the average achievement of the young group did not differ significantly from the average achievement of the middle group. Similarly, research suggests that retention in kindergarten or first grade may be associated with poorer academic and social functioning throughout the elementary grades and even into young adulthood (Alexander et al., 1994; Jimerson, 1999; Jimerson et al, 1997; Mantzicopoulos, 1997). Differences in achievement related to age exist to some extent in elementary school but tend to diminish and even disappear by middle school. Additionally, May, Brogan, and Knoll (1993) found no relationship between the children's birth dates and later classification as handicapped. Profiles of children who are retained in kindergarten indicate that they have multiple deficits and needs, making it unlikely that simple exposure to the same curriculum would be an effective intervention (Alexander et al., 1994; Mantzicopoulos, Morrison, Hinshaw, & Carte, 1989).

Many schools have adopted transitional or developmental programs for children "not ready for first grade." However, those programs appear to be no more effective than retention (Dennebaum & Kulberg, 1994; Ferguson, 1991; Ferguson & Streib, 1996; Gredler, 1992; Mathews, 1977; Talmadge, 1981). Zinski (1983) found no significant differences between children who attended a transitional program between kindergarten and first grade at the end of first grade and children who repeated first grade. Gredler (1983) reviewed seven studies that investigated the effects of transition room placement and concluded "research indicates that transition room children either do not perform as well or are at most equal in achievement levels to transition room-eligible children placed in regular classrooms."

A comprehensive review of the effects of retention was conducted by Holmes and Matthews (1984). They conducted a meta-analysis of 44 studies, calculating 575 effect sizes to determine the effects of retention on a variety of factors, such as achievement, personal adjustment, self-concept, and so on. The authors defined effect size as "the difference between the mean of the retained group and the mean of the promoted group, divided by the standard deviation of the promoted group." Meta-analysis has become a popular way to aggregate a large number of studies that investigate a common research question.

All the studies selected by Holmes and Matthews compared a group of retained students with a group of promoted students. Thirty-three of the studies investigated achievement effects. Those studies yielded an overall effect size that indicated that retained students scored significantly lower than promoted students on achievement measures. While teachers believe that retention in the grades kindergarten through third grade is not harmful (Tomchin & Impara, 1992), when Holmes and Matthews analyzed the data by the grade levels in which the retention took place (grades 1–6), they found negative effects at all grade levels. This calls into question the commonly held belief that the earlier a student is retained the greater the likelihood that retention will produce positive effects.

While proponents of retention maintain that promoting children when they are not ready can have a harmful effect on personal adjustment, the bulk of the research does not support this contention. In addition to achievement effects, Holmes and Matthews (1984) also calculated effect sizes on personal adjustment measures taken from 21 studies. They found negative effects for social adjustment, emotional adjustment, and behavior, as well as self-concept, as did another study on the long-range effects of retention (Thomas et al., 1992). Many studies have found that students' attitudes toward retention are negative. Byrnes and Yamamoto (1984) found that children who are retained recognize the change as failure and feel ashamed. In their study children rated retention behind only blindness and a parent's death as most stressful experiences. Smith and Shepard (1989) reported that clinical interviews with retained students indicate these students saw their retention as "flunking" and as punishment. In this same study, parents of retained kindergartners reported that their children experienced teasing and adjustment problems because of their non-promotion. Johnson (1991) argued that children who have failed in school show characteristics of learned helplessness. The students in his study were likely to attribute failure to themselves and to deny responsibility for success.

Jimerson (2000) summarized studies on retention between 1990 and 1999, systematically reviewing 19 studies that met a standard set of criteria for inclusion (published in a professional journal, addressed the impact of early grade retention on achievement, socio-emotional development or other factors, and included an identifiable comparison group of promoted students). A meta-analysis was conducted with these studies examining academic achievement and socio-emotional development and looking for effect size differences; that is, a measure of the benefit or harm of the intervention between the retained and comparison group across studies. Results examining achievement differences were very similar to the results of Holmes' earlier meta-analysis. Of 173 analyses that explored academic achievement, 9 found that retained students outperformed the comparison group of promoted students, 70 found that the comparison group outperformed the retained students, and 94 yielded no statistical differences at all. Only three of the nine analyses favoring retained students considered outcomes beyond the repeated year.

Results examining socioemotional and behavioral outcomes were explored in 16 studies yielding 127 analyses. Of these, 108 yielded no significant differences between the retained and the matched comparison group. Thirteen significantly favored the comparison group, while 6 favored the group of students who were retained. Jimerson (2000) notes that while the overall effect size for emotional adjustment was much higher than Holmes' 1989 meta-analysis, the social and behavior adjustment was similar and that additional effect size calculations show the retained group with overall lower ratings of adjustment, lower ratings of self-concept, and lower school attendance. Overall, 12 of the 19 study authors drew negative conclusions about the efficacy of retention. Four study authors drew favorable conclusions. However, these authors agree that retained children were still not successful at school—seeing retention as a way of lessening incompetence, at least temporarily, not creating competence—and all argue for additional remedial strategies. In other words, no authors conclude that early retention alone can solve the problem of academic failure and most conclude that it will not benefit students and may actually harm them.

Secondary Level

At the secondary level (i.e., middle school, junior high school, and high school) students are most often retained for two reasons: a lack of sufficient credits to be promoted to the next grade level or to graduate from high school or a failure to pass mandated minimum competency exams. The sources of these failures lie in either the students failure to learn to read effectively in the primary grades; a student's inability to develop the organizational, metacognitive, and study skills necessary for success in the upper grades; or a devastating combination of the two.

Through the sixth grade, retention rates tend to decrease with each year. However, when students reach the seventh grade, retention rates rise and continue to increase in subsequent years (Medway & Rose, 1986; Rafoth & Carey, 1991). Generally, the increase in retention rates is due to students' inability to meet the school district's standards for promotion or to obtain sufficient credits to graduate from high school. Often these students have received failing grades, have demonstrated higher absenteeism than their promoted peers, have been retained in earlier grades, and have experienced higher rates of discipline incidents (e.g., suspensions) (Fleming & Zafirau, 1982). Alternative education is often not provided to these students, and for many life outside of school becomes more important.

Perhaps prompted by employers' doubts about the meaning of a high school diploma and society's current attitudes toward perceived deficiencies in the U.S. educational system, many states now require students to pass minimal competency exams to receive a high school diploma. However, many students are unable to pass these tests because of poor reading skills and/or academic performance, and retention becomes the "intervention" of choice. Once retained, remediation often does not occur during the student's retained year, and the student makes little, if any, gains in academic performance. Many school policymakers believe that retaining students unable to pass minimum competency tests will motivate those students to improve skills and complete the necessary requirements for graduation. However, students are often not motivated by retention and once they have experienced retention, they often equate the circumstance with failure, view themselves as failures, and thus drop out of school. It appears that setting higher standards and administering competency testing do not improve the academic performance of students most at risk for school failure. Instead, these actions may result in an increase in the number of students who are retained and drop out of school (Hamilton, 1986).

Research on retention at the secondary level has generally examined the relationships between grade retention and attendance, suspension, and self-concept, with an emphasis on the correlation between retention and dropout rates (Rumberger, 1995; Shephard & Smith, 1990; Wehlage & Rutter, 1986). Retention rates at the high school level are related to attendance and suspension rates (Fleming & Zafirau, 1982). Generally, students who are failing do not attend school on a regular basis. In addition, students who have been retained prior to the secondary level are less likely to attend school on a regular basis in junior and senior high school. Additionally, regardless of the grade in which retention occurs, secondary students who have been retained often exhibit low self-esteem. In a follow-up study of high school students with a history of grade retention, Hagborg, Masella, Palladino, and Shepardson (1991) found that retained students were lower on a number of variables, including achievement, intelligence, and grades, and were more often absent from school and scored lower on a measure of self-esteem than did non-retained peers. They did note that students retained later in their educational careers displayed even lower grades, less positive school attitudes, more discipline problems, lower self-control, and a more externalized locus of control. General conclusions drawn from many studies suggest that retention correlates negatively with students' self-concept, peer acceptance, and personal adjustment.

The majority of the research on retention at the secondary level has focused on the relationship between retention and dropping out of school. Shephard and Smith (1990) reported that students who drop out are five times more likely to have repeated a grade than students who eventually graduate. Studies that conclude that retention is associated with dropping out are numerous (Cairns, Cairns, & Neckerman, 1989; Ensminger & Slusarick, 1992; Fine, 1991; Roderick, 1995; Rumberger, 1995). Being retained twice virtually guarantees a student will drop out of school, and grade retention alone has been identified as the single most powerful predictor of dropping out. This relationship can be explained by two competing hypotheses: (a) Repeating a grade may increase the risk of dropping out or (b) poor achievement may account for both retention and dropping out.

In many early studies undertaken to analyze the relationship between retention and dropping out of school, the achievement variable was not controlled. However, in a number of more recent studies (e.g., Grissom & Shepard, 1989; Jimerson 1999) the achievement variable was adjusted in order to focus only on the relationship between retention and dropping out. It has been found that the dropout rate of overage students (retainees) is appreciably higher than the dropout rate of regularly promoted students when reading achievement scores are equivalent for the two groups. Even in high-socioeconomic school districts, where students are less likely to leave school, a significant increase in dropout rates has been found for retained students. Jimerson (1999) found that retained students had a greater probability of poorer educational and employment outcomes in late adolescence when compared with low-achieving but promoted students, including levels of academic adjustment by eleventh grade, dropping out by age 19, receiving a diploma by age 20, enrolling in a postsecondary education program, receiving low educational/employment status ratings, being paid less per hour, and receiving poor competence employment ratings at age 20.

Do Some Children Benefit From Retention?

Sandoval and Hughes (1981) found that the children who made academic and social gains after repeating first grade had not experienced serious academic deficits in the year prior to retention, had strong self-esteem and social skills, and had shown signs of difficulty in school because of lack of exposure to academic materials (e.g., because of high absenteeism, illness, or frequent family moves) rather than low ability. In a 5-year follow up, Sandoval (1987) found that these same factors predicted success in the upper grades. However, Smith and Shepard (1989) make two points about this study: The fact that relatively high achievement and high self-concept prior to retention correlated with positive outcomes implies that the most successful retainees are those who need it the least. Even the most successful retainees are no better than promoted controls on a variety of outcome measures at the end of first grade. Dawson (1998) reviewed the literature and concluded that the general consensus is that while there may be individual children who benefit from retention we cannot predict who they are. Students who benefit from retention are more likely to have had additional educational interventions such as after-school tutoring, and a specific remedial plan beyond simple retention. Because these additional interventions were not provided for matched groups, it is difficult to ascertain whether the retention or the interventions produced positive effects.

At times, retention is employed in an attempt to postpone or supplant special education. However, there is little evidence to support the use of retention in this way (Barnett, Clarizio, & Payette, 1996; Carstens, 1985; Chandler, 1984; Lieberman, 1980). Cross (1984) found that the most important factors governing a teacher's decision to recommend retention were failure to complete a primer designated by the school district, general immaturity, and anticipated resistance to retention from the child's parents. Cross found that there were no differences in the reading achievement test scores of the children recommended and those not recommended for retention, and none of these factors has been shown to be useful predictors of successful retention.

Some researchers have believed it possible to predict which students benefit from retention and have encouraged schools to develop decision-making procedures to aid in selecting likely candidates (Lieberman, 1980; Light, 1977). Others have rejected such a process. Smith and Shepard (1987) conclude from their own research and their review of the literature, "Although some small percentage of those retained may be helped, the evidence indicates that educators are simply unable to predict accurately which individuals these will be." In addition, students who are retained report being teased, and the majority (84%) of first graders in one study said they would feel "sad," "bad," or "upset" about being held back (Shepard & Smith, 1990).

BEST PRACTICES

Alternatives to Retention

School psychologists' involvement with retention practices can occur on several levels. It can range all the way from participating in making retention decisions about individual students to influencing school or district-wide retention policies to lobbying for change on a state level through the collective efforts of a state school psychology association. An important effort at each of these levels should be to promote systemic approaches to reduce academic failure and the use of alternatives to retention that will not put students even more at risk by making them old for grade.

Promoting Systemic Solutions

The only real solution to the retention/social promotion debacle is to eliminate most serious academic failure before it occurs. This can only happen when the problem is attacked from a system-wide approach with careful attention to developmental issues and the findings of research on the efficacy of various forms of intervention. The use of screening assessments in preschool and kindergarten to identify students who may be at-risk for academic failure, particularly in the area of phonemic awareness, has been shown to be a sound method of predicting which children will have difficulty learning to read (National Institute of Child Health and Human Development, 2000). Similarly, reading interventions that provide intensive, early, and individualized help that targets a child's specific weaknesses (e.g., Success for All, Reading Recovery, Direct Instruction), (Slavin, Karweit, & Madden, 1989) have been shown to be effective in reducing early reading failure. The use of learning strategies instruction has been shown to be very effective in improving study skills and performance in middle school students. Inability to organize and study independently are often key factors in academic failure at this level (Forness, Kavale, Blum, & Lloyd, 1997). Inability to read effectively and to learn to study independently often leads to failure at the elementary and middle school levels and creates profound motivation problems at high school that contribute to the ultimate school failure; that is, dropping out. Systemic approaches to solving the problem of serious academic failure must target each of these areas from a developmental perspective that seeks to increase academic success at each major educational level (elementary, middle, and high school) by ensuring that more students are able to meet major academic task demands.

Individual Retention Decisions

School psychologists can be important participants when decisions are made about retaining students in their schools. They should help evaluate the reasons for school failure by looking at the children's school and developmental histories, the effectiveness of the instruction they have received, and the remediation strategies or programs available to them. The school psychologist should help plan an appropriate instructional program for the following year, whether or not the student is retained, and should act as a consultant both to parents and to school personnel to help them make retention decisions.

Two case discussions may help illustrate the part the school psychologist can play in making retention decisions. In the first case, a child whose first-grade teacher recommended retention was referred by her parents to the school psychologist for testing to rule out the possibility of a learning disability. The teacher reported that the student was having difficulty getting beyond the primer level in reading, her attention span seemed somewhat short, she had some trouble completing work independently, and she also seemed to be exhibiting some "immature behaviors," such as fidgeting in her seat and putting her fingers in her mouth. The child, an attractive, petite girl, was assessed as having average intelligence with achievement commensurate with her ability. The school psychologist met with the child's teacher and parents. She reviewed the test results and then led a discussion about retention. She summarized the research on retention, stressing that there is little evidence that it helps over the long term. She indicated that initially students who are retained in first grade show some improvement over similar students who are not retained but that these gains tend to disappear by third grade. She noted that the child's teacher was trying to make the best decision for the child as she could precisely because she was worried about the child's progress in the coming year, thereby lending support to the teacher without necessarily espousing her recommendation.

The school psychologist reported that while some children do seem to benefit from retention, at present educators lack the ability to predict reliably just which children will benefit. Therefore, she stressed to the child's parents that it would be important that they feel comfortable with whatever decision they made, since undoubtedly the child would sense her parents' comfort or discomfort with the decision. This statement was emphatically echoed by the child's teacher. The decision was left in the parents' hands. The mother later reported to the school psychologist that she had decided not to have her daughter retained. She indicated that as a child she had matured at a young age and she was worried that the same would happen to her daughter. She was concerned about the effect of early maturation, particularly if her daughter were already a year older than most of her classmates. While this parent decided to have her child continue on to second grade, she wanted to be sure her child would be able to get supplemental reading services and that her teachers would continue to monitor her progress in reading.

In a second example, a school psychologist became involved in the case of a kindergartner being considered for retention. In this case, the school psychologist led a team discussion, first questioning why retention was being considered. The classroom teacher pointed out that the child had spent most of the year in kindergarten with an undetected hearing loss, and, hence, it was unclear how much the student had been able to benefit from instruction. The school psychologist then referred to the section of the NASP Position Statement on Student Retention and Social Promotion (see Position Statement at the end of this volume), which specifies when retention is less likely to be harmful. She went down the list: Does this student lack serious academic skills deficits? Does the student have positive self-esteem and good social skills? Has the student had difficulty in school because of lack of access to instruction? The group decided that the answer to these questions was yes, and, hence, this youngster might benefit from retention.

Most parents and educators are unaware of the research on retention. The school psychologist should be willing to share this research to help schools and parents make informed decisions. This information should not be imparted dogmatically or in a way that impairs working relationships with colleagues or parents. In some cases, this may mean recognizing that schools will make decisions to retain children when the school psychologist feels it is not in the best interest of those children. Especially in these cases, it will be important for the psychologist to participate in developing a specific plan of action by which the student's skills deficits can be remediated. School psychologists are encouraged to gather follow-up data on children who have been retained and of children of comparable achievement levels who are not retained to help their school districts better understand the outcomes of retention decisions.

School District/System Level

School psychologists' participation at a school district or system level can take many forms. As within their own schools, they can publicize the research on retention to help guide the development of informed policies. They can also serve an evaluative role, using district-wide data to assess the outcomes of retention decisions. And they can monitor the progress of students to ensure that problems are identified and addressed early, before retention becomes a consideration. School psychologists can also promote the development of effective alternatives to retention at all grade levels, from preschool through high school. These can include both developing programmatic interventions that address the needs of failing students and expanding the capabilities of classroom teachers to meet the needs of students at different skill levels.

Programmatic interventions may include developing screening programs to identify children at risk for school failure and to ensure early access to programs already available in the school or community, such as Head Start, Chapter I services, and remedial programs. It may also include developing intervention programs such as after-school tutoring or summer school courses. However, such programs may not be sufficient to make up serious deficits in short amounts of time and cannot take the place of preventative, systemic approaches. At the secondary level, school psychologists should encourage the development of re-entry programs for dropouts and alternative education programs, such as ones that combine teaching skills with job training. Successful programs at the high school level often have two characteristics: (a) one or more individuals who develop relationships with students individually and monitor their progress carefully and (b) some mechanism to allow students who have failed courses and lost credits to regain these credits in quicker than normal time, allowing for graduation at the expected time. Simply put, successful programs must address the motivational issues that have developed by adolescence and the lack of academic achievement identity typically present in students who drop out of school.

Because unsuccessful middle and high school students often lack basic strategic learning skills, intervention programs should also target these areas. One program, titled, "Share the Secret," trained peer tutors to be study skill coaches as well as help their target students with classroom work and content. Tutors (successful students themselves) were told "to share the secret" of learning and studying that enabled them to succeed academically. Students who received tutoring were high-risk students who received tutoring several times a week during assigned study halls. Overall, the study skills component positively impacted student achievement and attitude (Rafoth, 1998).

The instructional technology that enables classroom teachers to meet the needs of students of different skills levels is already available, but in many cases teachers do not have access to that technology. School psychologists can assist their school districts in learning about this technology and arranging for in-service programs to bring this information into the classroom. Instructional approaches such as mastery learning, adaptive education, team teaching, cooperative learning, peer tutoring, and curriculum-based assessment are all methods that have been shown to produce academic gains in students of all achievement levels.

Two examples of such approaches are one school district's decision to respond to high numbers of retentions in the early grades by implementing a curriculum-based assessment and remediation program to correct basic reading problems. The district, with state support, secured an outside consultant, conducted intensive in-services for teachers, and allowed a local school psychologist to develop expertise in the area and become an on-site leader. Enlisting community support to volunteer to review sandwich word drills with students garnered both help and excitement in the community. Children made substantial progress, teachers were excited by a new intervention method, and requests for retention dropped dramatically.

Similarly, another district has begun a system-wide program to provide inservice instruction to teachers in fostering metacognitive awareness and learning strategies in students, by helping teachers learn about metacognitive development and study skills training and learn how to embed instruction in these areas into their everyday teaching. Collaborative monthly meetings with a consultant and the training of Chapter I teachers to become on-site experts proved essential to this program's success. The program having been established at the primary level, the teachers in this district now speak less of retention and more of enabling strategies that can be carried over from grade to grade with at-risk students.

To be taught and implemented effectively, the program must gain from school districts a commitment to providing sufficient in-service training. School psychologists are often effective lobbyists for such continuing professional development. In making arguments for such training, school psychologists should help school administrators recognize the economic benefits of reducing retention rates. Given the annual cost of retaining a child (an average of $6,000 per year per student), if a school district, for instance, retains 30 students annually, adding 1 year to those students' school careers will cost districts or state educational agencies about $180,000 each year. There is no doubt that quality training for teachers and many specific interventions can be obtained at a far lesser cost.

Another district reduced retentions dramatically by putting in place a collaborative, problem-solving team to deal with problems before the necessity of referral. Retentions dropped from a peak of over 40 in the 1983–1984 school year to just six in the 1990–1991 school year in three elementary schools with an enrollment of 1,500. In addition, after the new model was put into place (through efforts of the local school psychologist), referrals not leading to special education placements and out-of-district placements also declined from 30 to 5, and from over 100 to less than 50, respectively, in a 5-year period.

State Education Agencies

As advocates for children, school psychologists can often be most effective when they move beyond the realm of their own schools and school districts to work at a state level to bring about change. The discrepancy between what is known about retention and what is practiced is great enough to warrant action at a higher level. While a school psychologist acting alone cannot influence state policies and practices, change can occur through the efforts of a state school psychology association.

School psychology associations are encouraged to share the research on retention with their state education agencies and with other professional education associates (such as state principals' and superintendents' groups). They are also encouraged to use the lobbying resources available to them to influence legislation, including funding for alternative services delivery and legislation that affects policy, such as decreasing the rigidity of minimal competency requirements.

SUMMARY

Recent reviewers have concluded that there are no clear benefits to retaining students and that the practice can have deleterious effects on students' achievement, self-concept, attitudes, high-risk behavior, and can increase the likelihood of dropping out of school. Research conducted since the release of the original NASP Position Statement on Student Retention and its subsequent revision has continued to support these findings. Although it is possible that a small percentage of students retained may benefit, it is impossible to predict which students those will be. Delayed entry into kindergarten and use of transition rooms before first grade are no more effective than retention, and whatever initial benefits may be derived from retention after kindergarten or first grade appear to be washed out by the end of third or fourth grade. Meanwhile, there appear to be dangerous correlations with many high-risk behaviors for students who are old for grade. School psychologists should assist in making retention decisions about individual students and should promote effective alternatives to retention. Most important, school psychologists must press for systemic solutions that target early reading deficits, independent learning skills, and motivational problems from a developmental perspective. Working to change school practices in the area of retention will require sharing the research on retention with educators, conducting evaluations on the outcomes of retention decisions at the local level, and lobbying at the state level to promote changes in policy and to advocate for alternative service delivery systems that more effectively meet the needs of students experiencing school failure.

ANNOTATED BIBLIOGRAPHY

Dawson, P. (1998). A primer on student grade retention: What the research says. *Communiqué, 26*(8) 28-30.
This article is brief and comprehensive. It succinctly summarizes recent research on retention and presents the supporting case for the NASP Position Statement on Retention and Social Promotion. Demographic information is included as well as the impact of retention on self-esteem. Delayed entry to school and transition room placements are discussed in addition to the long-term effects of retention.

Gredler, G. (1992). *School readiness: Assessment and educational issues.* Brandon, VT: CPPC Publishing.
This book is divided into four sections that include (a) an introduction and review of the concept of school readiness (b) an assessment of readiness through screening measures and their validity and usefulness and the emotional and social adjustment of "young"-for-age children, (c) current practices in the schools such as variation in entry age and its effect on achievement; the use of transition rooms between kindergarten and first grade, retention, intervention/remediation programs for young children, and issues in early childhood education, and (d) related legal and ethical issues concerning readiness and early retention. It offers a comprehensive overview of all issues that touch on the practice of retention at the beginning of a child's education. He concludes that transition rooms and early retention are not effective and discusses alternatives.

Holmes, C. T., & Matthews, K. M. (1984). The effects of non-promotion on elementary and junior high school pupils: A meta-analysis. *Review of Educational Research, 45*, 225–236.
This study employed meta-analysis to integrate the findings of 44 studies investigating the effects of retention on elementary/junior high students. The results established consistently negative effects of retention on achievement, personal adjustment, and attitude toward school. The authors conclude, "Those who continue to retain pupils at grade level do so despite cumulative research evidence showing that the potential for negative effects consistently outweighs positive outcomes."

Jimerson, S. R. (2000). Grade retention review 2000: New directions for research and practice in the 21st century. Paper presented at the National Association of School Psychologists Conference, New Orleans.
This paper presents a comprehensive review of the research examining the academic and socioemotional outcomes of early retention. Studies published between 1990 and 1999 are summarized . A meta-analysis of 19 of those is presented. The results of this review are con-

sistent with previous findings that do not support retention as an effective intervention.

Smith, M. L., & Shepard, L. A. (Eds). (1989). *Flunking grades: Research and policies on retention.* New York: Falmer.

This volume provides a comprehensive review of the literature as well as a discussion of the editors' own research addressing policy and practice in student retention. Particularly noteworthy is their discussion of the relationship between retention and school dropout, in which they demonstrate that students of comparable achievement levels are more likely to drop out of school if they have been retained than if they have been promoted. The book concludes with recommendations for alternatives to retention.

51 Best Practices in Planning Interventions for Students With Reading Problems

Laurice M. Joseph
The Ohio State University

OVERVIEW

The majority of students who are referred for academic concerns and/or have been identified as having a specific learning disability have difficulties in the area of reading. Among the population of students with learning disabilities, an estimated 80%have reading disabilities (Lerner, 1993). Students with poor reading skills are becoming more apparent to educators and parents due to the results found on criterion-referenced, high stakes mandatory testing that most schools nationwide have incorporated across grade levels. The National Assessment of Educational Progress (NAEP; 1997) reported that 40% of fourth graders, 30% of eighth graders, and 25% of twelfth graders were reading below grade level. The percentages are even higher and the gaps even wider between grade levels in schools predominately made up of free or reduced lunch eligible student populations (Snow, Burns, & Griffin, 1998). Therefore, it is imperative that school psychologists work with a team of professionals to help students with reading problems by designing interventions from data-based decision-making activities. While data based decision-making practices will be touched upon briefly to establish their important link to targeting interventions, another chapter in this volume more fully addresses diagnostic and assessment issues in the identification of students with reading problems.

This chapter addresses intervention needs of students who have been formally diagnosed with reading disabilities. It also addresses students who may not meet formal criteria for a learning disability in the area of reading but who struggle with identifying and comprehending written language. Moreover, this chapter is congruent with the consultation/problem-solving orientation toward the practice of school psychology and discusses data-based intervention planning without placing emphasis on formal classification. Problems in reading can affect performance across several academic content areas, occupational endeavors, and other functional skills that are used in everyday life activities. The task of the school psychologist is to work with teachers and parents to define those problems through data-based decision-making methods, to target interventions to address the problems, and to help implement and evaluate those interventions. Specifically, this chapter will describe briefly the characteristics associated with reading problems, delineate a problem-solving/data-based decision-making process to develop effective interventions, and finally focus on a variety of interventions that can be used to address different types of reading problems.

BASIC CONSIDERATIONS

Characteristics of Students With Reading Problems

Two types of students with reading problems that school psychologists and educators are likely to encounter are students with IQ-reading achievement discrepancies and students with a combination of low ability and low reading achievement. Students who have IQ-reading achievement discrepancies tend to have average to high average IQ and listening comprehension scores (Aaron & Joshi, 1992). Children with developmental dyslexia are included in this group of poor readers. Dyslexia is often associated with some neurological impairment that results in poor word recognition skills including phonological processing. Slow rate of reading, erratic oral reading, misuse of function words and suffixes, and reading comprehension difficulties on timed reading tasks are among the symptoms commonly associated with dyslexia (Aaron & Joshi, 1992).

Low ability readers make up the largest number of poor readers. They tend to have lower than average IQ and have below grade level listening comprehension, word recognition, and reading comprehension performance. Although we tend to classify children with severe reading problems as low ability readers or IQ-achievement discrepant readers, current research indicates that there are no significant differences between these two groups of readers on how they develop reading precursor skills (Wristers, Francis, Foorman, Fletcher, & Swank, 2000). Earlier research conducted by Stanovich and Siegal (1994) also suggested that IQ did not predict reading difficulties among low ability (garden variety readers) and IQ-discrepant readers. Instead, they found that phonological core variables were better predictors of reading skills. Therefore, differential diagnoses based on IQ scores do not yield different growth patterns in reading development. For this reason, the remainder of this section will describe poor readers according to specific cognitive processes and behaviors they exhibit rather than according to diagnostic categories.

Poor readers with word recognition difficulties generally over rely on textual cues such as pictures and other words to identify words in a passage that are unknown to them (Kim & Goetz, 1994). Overusing textual cues to identify unknown words reduces the likelihood of transforming unknown words into sight words (Pressley, 1998). Many errors are made when children use semantic contextual approaches rather than sounding out words. Children need opportunities to sound out words even if this means they have to struggle (Adams & Henry, 1997). This may be easier said than done as many children do not know how to begin to sound out words. Some poor readers have limited letter-level knowledge or an understanding of the alphabetic principle. Typically, these types of readers are limited to being able to sound out only the beginning letter of a word.

The inability to sound out words can be attributed to phonological processing difficulties. Weak phonological processing accounts for the largest population of students classified as having dyslexia or individuals with severe word recognition difficulties (Pressley, 1998). Phonological awareness is a crucial component to becoming literate. This has been verified through studies that examined long-term effects of phonological awareness training in preschool and kindergarten on subsequent reading achievement performance of first, second, and third graders (Ball & Blachman, 1991; Byrne & Fielding-Barnsley, 1993). Phonemic awareness is knowing that spoken language is made up of discrete, operable sounds. Rhyme production, sound blending, sound deletion, sound substitution, and sound segmenting are among the many ways individuals can operate on spoken words. Developmentally, children begin with rhyme activities and then progress to segmenting sounds in words. Among phonemic awareness exercises, phonemic segmentation is the best predictor of word identification for primary grade children (Nation & Hulme, 1997). An example of a phonemic segmentation exercise would be to pronounce a word such as "cat" and ask a child to say each sound as three separable sounds in the word such as /c/ /a/ /t/.

Some children develop phonemic awareness through literacy experiences at home before entering school while others have limited exposure to print and role models who engage in reading and writing. Some children, regardless of their environmental conditions, struggle with grasping phonemic awareness. Thus, children who lack phonological skills and have a limited vocabulary will have difficulty phonologically "recoding" letters back into their constituent sounds when they encounter print (McCormick, 1999). When most children initially encounter a printed word, they go through a process of sequentially decoding the word by attempting to make letter-sound conversions. Phonological recoding occurs as children check to see if the word they made matches a word that has been stored in their memories (Daneman, 1991). At advanced stages of this process, children learn to decode words hierarchically. Hierarchical decoding involves using letters in words to cue the sounds of other letters. For example, using the "e" at the end of the word "came" to say the "a" as a long vowel sound.

Related to phonological recoding is orthographic processing. Orthographic processing refers to recognizing and remembering letters which includes noting sequences of letters in words and being able to distinguish among spelling patterns of words. Although smaller in population compared to those with phonological deficits, some children with reading and spelling problems have difficulty processing words orthographically (Stanovich & West, 1989).

Children need to become automatic at recognizing words to free up their cognitive energies to gain meaning from text. Poor readers not only struggle with recognizing words in text but also have difficulty suppressing irrelevant information in text which places limitations on the use of their short term capacity for comprehending printed material (Pressley, 1998). These students have particular difficulty grasping an understanding of texts that contain words with multiple meanings (McCormick, 1999).

Beyond the word reading level, poor readers have difficulty making inferences about the content presented in text. Poor readers do not connect ideas well and may not grasp the conceptual nature of the material. Problems with making inferences are partly due to poor readers' lack of prior knowledge about the content. On the other hand, good readers read more and gain more knowledge each time they read material.

Good readers also have a repertoire of comprehension strategies to help them construct meaning from text. Poor readers know very few, if any, strategies that aid in the construction of meaning from text and strategies for monitoring understanding of text (Pressley, 1998).

Collaborative Team Model

Regardless of their diagnostic label, poor readers get poorer without the benefit of effective instruction. This notion is what Stanovich (1986) coined the "Mathew Effects" in reading. In order to prevent the retention of weak literacy skills, appropriate stakeholders such as school psychologists, general education teachers, special education teachers, speech and language specialists, reading specialists, administrators, and parents need to initially establish collective efficacy about the relationship between instruction and performance. In fact, an increase in reading achievement occurred in schools where beliefs about teaching and learning competencies were shared collectively by stakeholders (Goddard, Hoy, & Woolfolk-Hoy, 2000). Once collective beliefs have been established, collaborative problem solving among interested stakeholders should occur within a data-based decision-making framework. In other words, the process of linking assessment to intervention needs to be shared by the appropriate multidisciplinary team members. Team members need to share the responsibility for determining students' skill levels, identifying instructional environment variables, targeting appropriate interventions, monitoring student progress as a function of interventions, and evaluating outcomes. These responsibilities are carried out though data-based intervention methods.

Data-Based Intervention Methods

Before describing interventions that help students with word identification and reading comprehension skills, it is imperative to discuss the bases for why some interventions are targeted for implementation over others. Decisions made without systematic data collection may result in targeting inappropriate interventions that further exacerbate students' struggles with reading.

When a student experiences difficulty with reading, professionals and other interested stakeholders (i.e., family members) should work in a collaborative fashion by collecting data to define the problem in observable terms. Data can be gathered through various methods according to the nature and severity of the reading problem. For instance, school psychologists may be responsible for conducting systematic observations of students engaged in oral reading and comprehension exercises. This is a good way to begin gathering data. Following observations, school psychologists may conduct interviews with students and teachers to uncover information that was not detected by observation. Teacher and student interviews can be helpful in gaining information about perceived expectations of competence in literacy and to ascertain efficacious behaviors toward meeting learning goals. Examples of teacher and student interviews can be found in Shapiro's (1996) *Academic Skills Problems Workbook*. Systematic observations coupled with interviews may be sufficient depending on students' needs or may further guide team members in choosing other appropriate reading assessments that are sensitive to specific difficulties as well as provide baseline measures of performance. Types of reading assessments may include informal reading inventories, curriculum-based measures, miscue analysis inventories, criterion-referenced tests, and standardized diagnostic reading achievement tests.

Practitioners are cautioned about the use of test scores derived from these assessments because they may not be as helpful for targeting interventions in contrast to the strategies students use or fail to use while attempting items involving identifying and understanding print. This is especially the case for students who are older and can identify words accurately but not automatically (Snow, Burns, & Griffin, 1998) and who may take a long time deriving correct answers to comprehension questions about text.

Once interventions are targeted and implemented from assessment information, treatment integrity needs to be assessed. This means that interventions need to be applied consistently as designed. For a comprehensive discussion about this important aspect of implementing interventions, please see Telzrow's chapter on intervention integrity in this volume. Progress monitoring of student performance over time is another critical component that needs to occur to assess whether or not interventions are effective for meeting students' literacy needs. Curriculum-based measures and other informal measures (e.g., teacher-made probes and informal reading inventories) that indicate specified criterion levels of performance can serve as appropriate assessments for progress monitoring of student performance. School psychologists may support teachers by helping them monitor student progress over time in a systematic fashion. Students should also be encouraged to engage in progress monitoring activities. Graphic representations of data may provide a visual description of whether interventions have been appropriately targeted and applied. The following case study illustrates the use of various assessments that aided in targeting an intervention and conducting systematic progress monitoring.

Case Study of Rick

Rick was a third-grade youngster with an attention-deficit hyperactivity disorder and learning disability in reading and written expression. His special education teacher consulted with the school psychologist about intervention suggestions for Rick. The school psychologist conducted systematic observations of Rick during oral reading and spelling activities. Observations revealed difficulty with making letter-sound correspondences while attempting to identify basic high frequency words with consonant-vowel-consonant patterns. A teacher and a student interview was conducted, and it was determined that Rick was provided with a buddy to read stories and to assist with classroom assignments. Rick reported that he would feel anxious about completing reading assignments if he did not have his buddy's assistance. Without assistance, Rick was asked to read and spell a list of 100 words with consonant-vowel-consonant patterns. It was determined from this assessment that Rick could only read 5 out of the 100 words on the list. Interestingly, he was able to spell 90% of the words on the list.

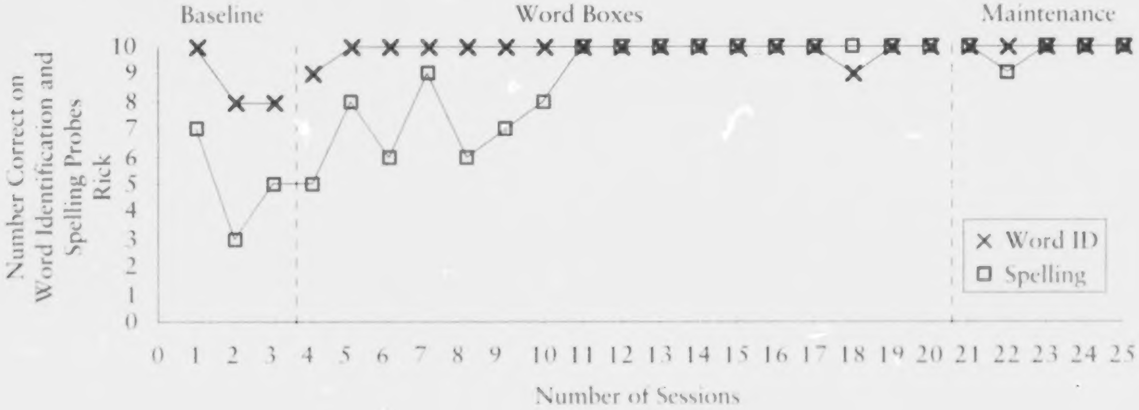
The school psychologist assisted the special education teacher in developing procedures including integrity checks during baseline, intervention, and maintenance sessions . Baseline word identification and spelling probes were developed and consisted of 10 words that were randomly selected from a list of 100 words. The 10-item probe was given over three sessions. It was determined that Rick's mean identification score was 5.0, and his mean spelling score was 8.6. Word boxes, an intervention described in detail in the intervention section of this chapter, was implemented to help Rick make letter-sound correspondences while attempting to identify words. Word identification and spelling probes were administered daily at the completion of intervention. They contained sets of words with consonant-vowel-consonant patterns taken from the list of 100 words. Rick obtained a mean score of 8.6 on word identification probes and 9.8 on spelling probes across instructional sessions. Maintenance probes were also administered, and Rick maintained a high level of performance on probes. Figure 1 depicts a graphic representation of Rick's word identification and spelling performance overtime.

BEST PRACTICES

This section provides a description of evidenced-based instructional interventions for students who have difficulty with word identification and reading comprehension. Since many educational professionals are likely to be aware of some of the traditional

794

Figure 1. Continuous progress monitoring of Rick's word identification and spelling performance



approaches to literacy instruction that have been used over many years, many of the approaches presented in this section will be those that are considered contemporary approaches for meeting the needs of diverse learners. Of course, the interventions described are not exhaustive of all approaches for the amelioration of reading difficulties. Please consult the resources listed in the annotated bibliography section of this chapter for further reading about any of the interventions presented in this chapter and for a description of other instructional approaches. For anyone thinking about implementing any of these interventions, it should be realized that "one size does not fit all." It may be desirable to modify or target other interventions based on sufficient data obtained about the unique needs of individual students.

General Components of Effective Instruction

Whether word identification or comprehension interventions are implemented, general psychological components of teaching and learning that apply to how children acquire literacy should be incorporated in lessons. Scaffolding, shaping, connecting to prior knowledge, constructing meaning, motivating students, and providing opportunities to learn have been considered among the key components of best literacy instructional practices (Gambrell, Morrow, Neuman, & Pressley, 1999). School psychologists can work collaboratively with educators by helping them incorporate the following critical components during instruction.

SCAFFOLDING

Several instructional approaches to word identification and reading comprehension employ scaffolding. Scaffolding, a term coined by Wood, Bruner, and Ross (1976), means that necessary support needs to be given to a child and gradually faded once the child approximates independent functioning while completing tasks. The concept of scaffolding is rooted in Vygotsky's (1978) notions about how the mind develops through interactions between teachers and students and how children may be able to achieve more than what was initially expected given the proper cultural tools. Examples of scaffolding include teacher facilitation and feedback as well as appropriate instructional materials that serve as supportive structures to make tasks solvable (Carnine, Silbert, & Kame'enui, 1990). Instructors who embrace scaffolding procedures often are those who view themselves and the materials they design or select as mediators of learners' development.

SHAPING

A behavioral concept that is similar to scaffolding is shaping. Shaping, a term described by Skinner (1957), means to elicit reinforcers for successive approximations toward completing an objective. Delivering reinforcers for efforts made toward achieving a goal can be considered as ways of providing support to students. This cannot be stressed enough when working with children with reading difficulties. Many children with severe reading problems will become extremely frustrated in the process of becoming literate because they will not experience success immediately. Reinforcers may not have been a systematic part of students' instructional histories. In other words, contingencies for reading behavior may have been inconsistent or delivered haphazardly rather than in successive approximations to desired reading behavior. These are the children who grow up and find reading not enjoyable and may not experience reading as a reinforcer (e.g., gaining information and pleasure). These individuals may later find themselves in limited employment and social situations. Therefore, it is crucial that educators and parents shape reading behaviors through praise and rewards contingent upon efforts made at achieving reading skills.

CONNECTING TO PRIOR KNOWLEDGE

Effective instruction includes being aware of what students know. Assessing student's prior understandings and experiences will help teachers facilitate links between what students know and what they need to learn. How quickly one grasps information presented in text depends largely on one's prior knowledge of the content (Gambrell et. al., 1999). Students with learning problems often have limited prior knowledge and experiences on which to "hook" new information. It is especially imperative that teachers provide opportunities for students to gain background knowledge through discussions and activities before students are presented with text that is foreign to them.

CONSTRUCTING MEANING

While specific literacy skills are important to teach, educators must keep in mind that the purpose of reading is to construct meaning from text. Capturing the plot of a story, following instructions for putting things together, and learning about current events are among some of the purposes for reading. Several scholars claim that children acquire decoding, spelling, grammar, and comprehension skills more easily if the context from which they are presented is personally meaningful (Gambrell et al., 1999). Higher-order reasoning and new meanings about text can result from children who were provided with meaning-based literacy activities at school and home.

MOTIVATING STUDENTS

Motivating students to read is a real challenge particularly for the upper elementary and secondary school teachers. Studies have shown that kindergartners and first graders are more likely to expend efforts toward reading even if they fail (Nicholls, 1990) while older students, especially those with learning difficulties, are less willing to put forth effort if they do not experience success (Jacobson, Lowery, & Ducette, 1986). Young children are more likely to attribute their failures to insufficient effort while older students who struggle with reading often attribute their failures to factors such as task difficulty and unfounded teacher perceptions (e.g., student feels teacher does not like him or thinks he is incapable).

Attribution retraining (i.e., helping students realize their efforts lead to desired outcomes) coupled with strategy instruction has been found to be effective for helping low achieving students improve on their use of reading strategies (Carr & Borkowski, 1989). Literacy activities should be authentic, integrated with other content areas, interesting, and occur within a social context so that students are motivated to participate in them (Pressely, 1998). This includes providing students with opportunities to choose from a range of high quality literature and to exchange dialogue about reading material (Palmer, Codling, & Gambrell, 1994).

PROVIDING OPPORTUNITIES TO LEARN

Within the time allotted for literacy activities, students need opportunities to make frequent responses during oral and silent reading as well as writing lessons. Students also need plenty of opportunities to practice new skills that are learned. This instructional component cannot be emphasized enough while students are acquiring literacy skills. Children with learning disabilities and mental retardation need more opportunities to practice than their peers (McCormick, 1999). Over-learning leads to transferring skills to other tasks more easily.

Word Level Interventions

Many students who experience difficulty identifying words are not aware that spoken words are made up of discrete sound units (Adams, 1990). Phonemic awareness exercises also help children operate on sounds of spoken language through phonemic blending, segmentation, deletion, and substitution activities. Phonemic blending exercises involve blending individual sounds or clusters of sounds together to form a whole word such as blending the sounds /c-a-t/ to form the word /cat/ and blending /fl-at/ to form the word /flat/. Segmentation exercise involves saying each individual sound in a word such as saying /t-a-p/ for the word /tap/. An example of a phonemic deletion would be removing the /f/ from the word /fin/ and saying the remaining sounds /in/, and substitution consists of adding a different sound (/b/) to the remaining sounds to make a new word (/bin/). Phonemic analysis exercises can involve identifying the position of sounds in words such as identifying the /a/ as the middle sound in the word /tap/.

The purpose of implementing interventions that target word level problems is to help children eventually read words by sight or with automaticity. Some children have difficulty reading words automatically because they do not possess strategies in making letter-sound associations. Word level interventions consist of phonics instructional approaches. Phonics incorporates methods by which children learn letter-sound associations. Stahl, Duffy-Hester, and Stahl (1998) stated that good phonics instruction consists of developing the alphabetic principle, developing phonemic awareness, providing familiarity with forming letters, and providing sufficient practice in reading words. They also indicated that good phonics instruction should not be rule-based and does not dominate literacy instruction programs. Many of the rule-based approaches used workbook exercises that required children to memorize and recall rules. Clymer's (1996) review of commonly used words in children's reading materials revealed that rules were rarely applicable to most words encountered in texts.

PHONIC APPROACHES

There are a variety of approaches to teaching phonics. Rule-based approaches are considered to be analytic approaches to teaching phonics (Cunningham, 1999). Children are taught some words and asked to analyze them by breaking the words down into their component parts followed by making phonic generalizations about the words. As alluded to previously, many basal reading programs that include accompanied workbooks are reflective of an analytic approach to teaching phonics (Stahl, Duffy-Hester, & Stahl, 1998). For example, students may read a list of words on a worksheet and mark whether the vowel in each word makes a "long" or a "short" sound. Synthetic approaches to teaching phonics, on the other hand, involve explicit teaching of letter-sound associations. During practice lessons, students pronounce sounds in isolation and then blend them to make words (McCormick, 1999). An example of an empirically supported synthetic phonics program is Direct Instruction (Adams & Englemann, 1996). This approach infuses behavior analysis principles of teaching children to systematically progress from one phonic skill to the next. Initially, individual sounds are taught and then children are asked to blend sounds to form words. Cueing, feedback, and opportunities to make many responses are provided during every lesson.

Drawing from decades of her own research, Cunningham (1995) advocated teaching phonics through primarily an anologic approach. In an anologic approach, children are taught to become word pattern detectors and use words or parts of words they know to figure out unknown words. For instance, if a child can read and spell the word "sit" then the student will also be able to read and spell the words "fit," "kit," "bit," "hit" and other words that belong to this family of words. Cunningham's Four Blocks program follows predominately an anologic approach to teaching phonics (Cunningham, 1999). The Four Blocks program is a combination of four major reading approaches that emphasize multilevel instruction. This program includes guided reading, self-selected reading, writing, and word study approaches. The word study approaches best illustrate the kinds of activities that would represent teaching phonics anologically. Doing the word wall, making words, and guessing the covered word are among some of the activities included in the word study portion of the program.

Doing the word wall consists of putting words up around the classroom where children can easily see them. Displayed words should be carefully selected and correspond to those that children commonly need in their writing. Only approximately five new words need to be added to the wall per week. Words that typically cause confusion can be written in a variety of colors so they stand out among those written in black. Children are asked to write and say the words on the word wall and complete a variety of review activities so words are read and spelled automatically.

Making Words activity consists of providing students with six to eight different letters on letter cards. The teacher says words with two, three, four, and more letters that can be formed with the letter cards. Children are then asked to use all of their letters to make a big word that is related to something they are reading. For instance, the teacher may give the students cards with a letter printed on each. The letters may be, s, a, p, l, r, e, t. The students are instructed to use the letters to form two-letter words and then three-letter words and so forth . At the completion of the lesson, the students are asked to use all of the letters and make a big word such as "stapler" (see Cunningham & Hall, 1994, for a thorough discussion of this activity).

Guessing the covered word consists of writing four to six sentences on the board and covering up one word in each sentence with a sticky note. The first sentence is read, and the students guess the covered word as the teacher writes down all the guesses. The teacher explains to the children that the covered word could be lots of different words when the letters are not shown. All of the letters are uncovered up to the first vowel. Guesses that do not begin with the beginning letters are erased, and the students are encouraged to continue guessing with the remaining words written on the board or make new guesses. Eventually, the whole word is uncovered as students' guesses approximate or match the covered word.

In the Four Blocks program, children are taught to rely on word study strategies to identify unknown words while reading texts (Cunningham, 1999). The words blocks activities can also be considered ways in which children study about words. In fact, these types and other similar approaches have been classified as word study phonic approaches and considered to be contemporary because they employ multisensory methods of helping children understand phonological and orthographic features of words (Stahl, Duffy-Hester, & Stahl, 1998). Other types of contemporary word study approaches include word sorts and word boxes.

Word sorts are an anologic phonic approach for helping children categorize words according to shared phonological, spelling, and meaning components. They can come in the form of closed sorts where the teacher establishes the categories or open sorts in which children induce the categories based on an examination of subsets of given words (Zutell, 1998). Words to be sorted are usually placed on index cards, and the established categories provide a structure for detecting common spelling patterns and discriminating among word elements (Barnes, 1989). Bear, Invernizzi, Templeton, and Johnston (1996) provide a comprehensive guide to creating various types of word sort lessons and other word study phonic activities. For instance, phonemic awareness sorts can be accomplished by having the children place tokens below given respective word categories as the teacher articulates words. Children can also spell words below respective categories as the teacher orally presents words. Howard Street (Morris, Shaw, & Perney, 1990) and Early Steps (Santa & Hoien, 1999), two effective tutoring programs for low achievers, incorporate word sort techniques rather extensively.

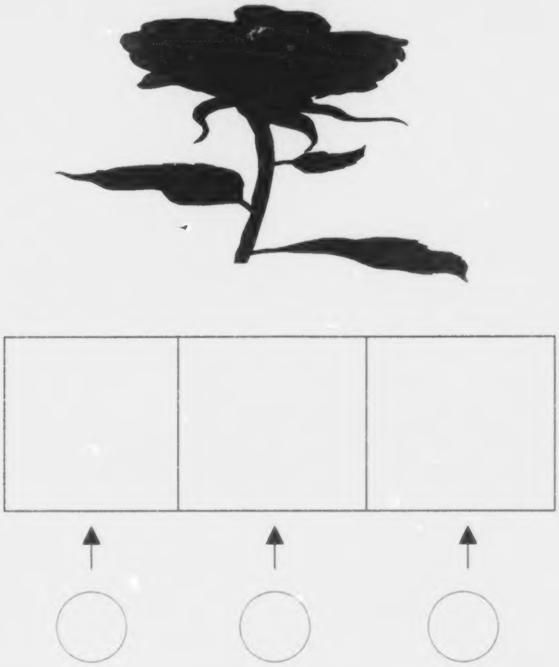
Word boxes, a synthetic phonic approach, helps children segment sounds of spoken language. This approach has been effective for helping children with learning disabilities identify and spell words (Joseph, 1998/1999). Typically, word boxes have been used within the comprehensive Reading Recovery program (Clay, 1993). A word box consists of a drawn rectangle that has been divided into sections (boxes) according to individual phonemes in a word. Initially, children place tokens in respective sections as each sound in a word is articulated slowly (see Figure 2). Eventually, children place letters (either magnetic or tile) in respective sections as each sound in a word is articulated. During advanced phases, children are asked to write letters in the respective divided sections of the box.

Joseph (2000) compared beginning first-grade children who were either assigned word boxes lessons, word sorts lessons, or traditional phonics lessons and found both word boxes and word sorts to be effective on children's phonemic segmentation, phonemic blending, word identification, nonsense word naming, and spelling in contrast to the traditional group's performance. There were no significant differences between the word boxes group and the word sort group. Controlled comparative research is still very young, and until more data are obtained, it is best practice to be flexible and choose from a variety of empirically based phonic approaches that facilitate the study of phonological and orthographic components of words.

SIGHT WORD RECOGNITION

A reciprocal relationship exists between developing sight word recognition and word identification skills

Figure 2. Phonemic segmentation phase of word boxes instruction. The word, "rose," has three sounds and, therefore, three connected boxes along with the same number of tokens are presented.



for reading new words. Once students are able to read a bank of words fluently, they can easily identify new words by analogy especially if letter sequences contained in words are similar. And, once children break sound to letter codes, they are able to read words more easily by sight or automatically especially if children engage in repeated readings of words (Samuels, 1988). Repeated exposures to words in multiple contexts are also important for storing words in memory and recalling them easily (Pressley, 1998).

Higher-Order Interventions

Higher order interventions include reading comprehension and concept attainment activities. Learning strategies instruction approaches were found to be effective for helping children with learning problems attain concepts and improve on their reading comprehension performance (Pressley & Woloshyn, 1995). Learning strategies instruction approaches that consist of self-questioning, constructing mental representations to integrate information from text, and identifying text consistencies were among the most effective comprehension strategies (Haller, Child, & Walberg, 1988). Examples of these approaches include semantic mapping, PQ4R (Preview, Question, Read, Reflect, Recite, and Review), and reciprocal teaching.

Semantic mapping typically involves developing word webs that reflect students' understanding of concepts and constructing a diagram connecting events of a story or connecting facts taken from content area textbooks (Novak & Musonda, 1991). Students who struggle with grasping conceptual relationships may find diagrams to be helpful visual aids. Semantic maps can be either process-oriented or product-oriented (McCormick, 1999). Process-oriented maps usually are completed before students read assigned material to help them establish some background knowledge. This type of mapping requires teacher facilitation of student responses. For example, a teacher may write a concept (e.g., satire) in a drawn box and ask the class to give examples of when they experience it. As the class responds, the teacher writes their comments below the concept.

The teacher may then ask the class how it feels when they witness the concept and write their responses, drawing connecting lines to the other comments, and so forth. Product-oriented maps, on the other hand, are produced by students as an outcome activity after they have read material. Students generally work independently or with other peers and construct a map connecting ideas presented in text. An illustration of a semantic map summarizing some aspects of North Carolina's beaches can be seen in Figure 3.

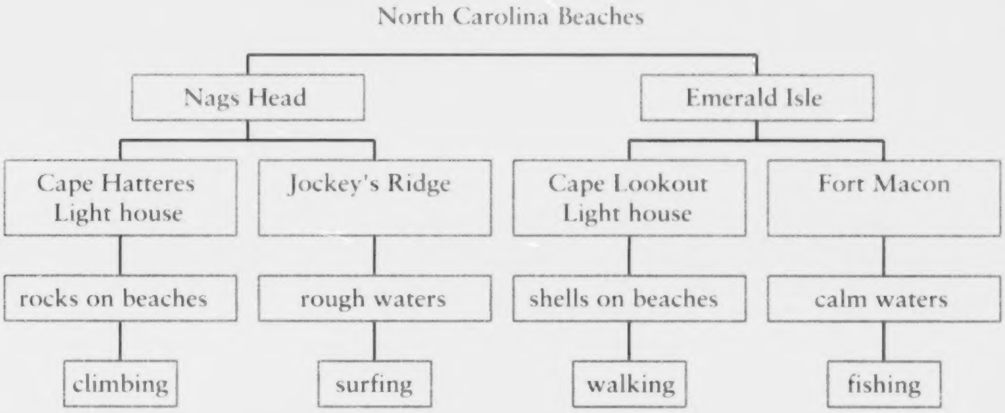
The PQ4R method of comprehending reading material is an extension of SQ3R (Survey, Question, Read, Recite, and Review) (Thomas & Robinson, 1972). This method involves previewing the reading material, questioning the reading, reading to answer the questions, reflecting upon the reading, reciting the reading, and reviewing the material. Previewing the material means surveying the chapter titles, main topics, and subheadings of the text. Students can turn the headings and subheadings into questions. Questions that were developed can be answered by reading the text. Reflections about the content can occur as the material is being read if the students pause to form connections and create images. Reciting is retelling what was read from memory. This form of retelling helps students monitor the information they are obtaining from the reading. If some information is not being retained, then students may need to read sections of the text again. Last, review the material by answering questions and referring back to the text for clarification of mistaken responses to questions. This method appears to be most appropriate for older students because it encompasses the application of higher-level metacognitive processes. Although PQ4R is not a new method, it continues to be considered as an effective technique for helping students organize and retain information from texts (Anderson, 1995).

Reciprocal teaching is a reading comprehension approach that has helped delayed readers catch up and even exceed typically developing readers (Palinscar & Brown, 1984). This approach places heavy emphasis on teacher-student interactions in a rather cognitive apprenticeship fashion. After students and teacher read from common text, they confer with each other about the reading material. Initially, the teacher leads the discussion by modeling strategies of predicting, question generating, summarizing, and clarifying text. The students are then asked to lead the discussions and apply the strategies that were demonstrated by the teacher. Guided practice is provided until students can use the strategies effectively. The goal of these reciprocal teaching interactions is to construct meaning from texts.

SUMMARY

The most frequent type of referral concerning students with academic problems is in the area of reading. Students with reading problems present characteristics that lend themselves to various instructional challenges. Some challenges of intervention design for the amelioration of reading problems lie at the word level, others lie at higher order

Figure 3. Semantic map of North Carolina's beaches



reading skills, and some lie with both. The best way to target appropriate interventions for children with reading problems is to conduct assessments that lead to appropriate data-based decision-making and problem-solving activities. Assessments that provide information directly linked to intervention design should be used with children who have been referred for having reading difficulties.

School psychologists play a vital role in meeting the needs of students with reading problems. By working collaboratively with teachers, parents, and other interested stakeholders to develop effective instructional interventions, school psychologists can be seen as part of the solution rather than the problem. In order for reading interventions to be effective, fundamental components of teaching and learning such as scaffolding, shaping, connecting to prior knowledge, motivating, and providing opportunities to practice skills should be implemented. Whether students are learning word level skills or higher order skills, mediations such as teacher facilitation and feedback are crucial to helping struggling readers become fluent. Teacher mediation and other cognitive tools can be seen through, for example, word study phonics, semantic mapping, and reciprocal teaching approaches.

In the past, school psychologists have often played a strong role in the diagnosis of children with reading problems. As our nation progresses into the twenty-first century where accountability of instructional and learning outcomes are at the forefront of objectives in most school systems, school psychologists need to move toward a proactive role of designing instructional interventions from data-based decision-making practices.

It is now time for best practices in school psychology to become the rule rather than the exception.

ANNOTATED BIBLIOGRAPHY

Aaron, P. G., & Joshi, R. M. (1992). *Reading problems: Consultation and remediation*. New York: Guilford.
This is one of the first books especially tailored to school psychologists consulting with teachers about students with reading problems. Aaron and Joshi describe psychological processes that contribute to reading acquisition. This book provides a thorough discussion about different types of reading difficulties including a very informative discussion about dyslexia. Intervention strategies for working with children who have word recognition, spelling, vocabulary, and comprehension difficulties are presented. An additional feature of this book is the practical guidelines for selecting basal series, reading tests, and tips for parents of children with dyslexia.

Bear, D. R., Invernizzi, M., Templeton, S., & Johnston, F. (1996). *Words their way: Word study for phonics, vocabulary, and spelling instruction*. Englewood Cliffs, NJ: Prentice-Hall.
This hands-on practical guide to designing word study lessons for helping children improve their phonological processing, vocabulary, and spelling is extremely user-friendly. More than 300 word study activities are presented in a mini-lesson format so professionals who directly work with students can readily reproduce and implement them in the classroom. Word study activities are included for all ages including preschool populations.

Gambrell, L. B., Morrow, L. M., Neuman, S. B., & Pressley, M. (1999). *Best practices in literacy instruction*. New York: Guilford.
This edited book contains chapters from many of the prominent scholars in the field of reading. An overarching theme of this book is the idea that literacy instruction should occur within an ecologically balanced curriculum. Instruction is described as a powerful tool and the teacher plays an important role as mediator in the development of children's literacy skills. Comprehension, writing, phonics, and the use of technology in literacy programs are emphasized in the various chapters. Links between home and school environments pertaining to the literacy needs of students are addressed.

McCormick, S. (1999). *Instructing students who have literacy problems* (3rd ed.). Englewood Cliffs, NJ: Prentice-Hall.
This is a very comprehensive book dealing with many aspects of students with reading difficulties. Types of reading programs are reviewed and etiology of reading problems is addressed. However, this book more comprehensively provides a wealth of information about various types of assessments (formal and informal) for the identification of reading problems including identifying students' strengths and weaknesses. The other large sec-

tion of the book deals with instructional interventions that can be readily applied by practitioners. Case studies are included throughout the book that illustrate the authenticity of the content. One of the best features of this book is the description of instructional approaches for students with extreme needs such as nonreaders.

Pressley, M. (1998). *Reading instruction that works: The case for balanced teaching.* New York: Guilford. This book provides a discussion about the whole language versus phonics debate and the need for comprehensive balanced literacy instruction. Pressley provides several chapters on the development of literacy that spans from infancy to the upper elementary grades. He also provides a chapter on the problems that children experience while learning to read. This includes some of the probable causes and symptoms of literacy failure. Pressley makes links between the process involved in becoming literate with attributional and motivational theories of learning. He concludes with some reflections about where the reading field has been and where it needs to be from an instructional perspective.

Best Practices in Contingency Management: Application of Individual and Group Contingencies in Educational Settings

Christopher H. Skinner and Amy L. Skinner
The University of Tennessee
Heather E. Sterling-Turner
The University of Southern Mississippi

OVERVIEW

Behavior analytic theory and research have proved useful to school psychologists who are committed to using empirically validated procedures for the assessment, treatment, and prevention of student problems within an educational setting. For example, behavioral assessment techniques have been shown to be advantageous because they (a) provide valid and direct measures of students' academic and social behaviors, (b) are sensitive enough to detect gradual changes in behavior, (c) can be used frequently with little time between assessments, (d) allow for within-subject analysis of behavior changes across conditions, (e) can lead to hypotheses regarding effective interventions for individual students, and (f) allow one to test and compare the effects of various interventions (see Shapiro & Kratochwill, 2000). Furthermore, a well-developed theoretical foundation and a plethora of behavioral interventions designed to alter behavior have been established and successfully applied across educational settings, students, and target behaviors (see Watson and Gresham, 1998).

In addition to developing theory and procedures, behavioral psychologists have developed a variety of single-subject research designs that allow school psychologists to conduct applied research in educational settings with individual subjects while controlling for threats to internal validity. Because most systems of intervention service delivery result in individual students being referred for idiosyncratic behaviors, these research designs may allow practicing school psychologists to alter students' behavior and contribute to the scientific database related to empirically validated interventions.

School psychologists can deliver services to students directly, as needs arise (e.g., individual therapy). However, the field of school psychology has been most effective recently in delivering prevention and remediation service through problem-solving consultation processes. Consultation with professional educators (e.g., teachers, administrators) often requires less time from the school psychologists than direct interventions. Consultation may be more effective because educators (a) work with the child on a regular basis within a student's natural environment and (b) may have more opportunities to implement intervention procedures. The process of consultation may also allow for the transfer of knowledge, skills, and attitudes, allowing educators to prevent and remedy future problems independently (Kratochwill & Bergan, 1990). Thus, it is not surprising that several models of behavioral consultation have been developed and shown to be effective for remedying students' learning and behavior difficulties (see Kratochwill & Bergan, 1990; Sheridan & Kratochwill, 1992).

The application of behavioral psychology within educational settings should increase when empirically validated treatments and consultation approaches to prevention and remediation are emphasized. However, the field of psychology appears to be in a cycle where the focus is shifting, or has shifted, from overt behaviors and environmental causes of behaviors to a focus on internal or subjective behaviors (Gibson, 1994; Robins, Gosling, & Craik, 1999). Although the degree of this paradigm shift is likely overestimated (Friman, Allen, Kerwin, & Larzelere, 2000), a similar trend is apparent within education, where internal constructs (e.g., information processing deficits, emotional intelligence or emotional quotients, learning styles, personalities, diagnostic categories, and developmental stages) have been and continue to be used to guide the development of intervention. Thus, pre-service educators may receive little training in behavioral theory and practice (Watson, 1994). Perhaps more disconcerting than lack of training, though, is when pre-service education professionals receive poor training and/or misleading information designed to discourage the use of behavioral theory and principles (Cooke, 1984).

Although paradigm shifts, psycho-educational fads, and training issues may partially account for the underutilization of behavior management procedures in general education settings, practical concerns may also play a role (Hall, 1991; Pumroy & McIntire, 1991). School psychologists have long recognized that if consultation models of service delivery are going to be effective, interventions must be developed and implemented within the context and constraints associated with classroom and school environments. Researchers investigating treatment acceptability have found educators prefer interventions that are time-efficient, fair, increase appropriate behaviors, and employ non-aversive approaches (Elliott, Turco, & Gresham, 1987; Lentz, Allen, & Ehrhardt, 1996). Additionally, interventions should be (a) effective, (b) either alter natural environments to support altered behavior or implement steps to encourage generalization and maintenance as part of the intervention, and (c) have an empirical research base that documents educationally valid changes in behavior within school settings (Stoiber & Kratochwill, 2000).

Unfortunately, many educators may associate contingency management procedures with individual behavior management programs designed to decrease inappropriate behavior levels (i.e., punishment programs). Although these programs have clearly been effective, they can be inefficient, reactive, aversive to students and educators, and considered unfair by educators, parents, and students. However, in many instances, positive contingency management procedures (i.e., positive reinforcement programs) can be designed to prevent and remedy both behavioral and academic problems. In addition to programs designed to address individual students' behavior, group contingencies can be used to design positive reinforcement programs that may better fit typical educational environments where educators are responsible to groups of students (Pumroy & McIntire, 1991).

In the next section, individual and independent-, interdependent-, and dependent-group contingencies will be defined. Applied strengths and limitations of these procedures will be described. Additionally, procedures designed to mitigate negative side effects associated with these contingencies and enhance desired effects within educational environments will be delineated.

BASIC CONSIDERATIONS

Although there are many variations of behavioral psychology (Baum, 1994), B. F. Skinner's operant behaviorism may have had the most influence on the development of applied behavior change procedures. Under an operant model, altering contingencies can change a student's behavior. Contingencies describe if-then relationships between behaviors and environmental antecedents and consequences. For example, a contingency contract may specify the following: When assigned homework (antecedent), Johnny will arrive at class the next day on time with his homework completed at 80% accuracy for 8 of 10 days (behavior and criteria). If these criteria are met, then Johnny will be allowed to engage in free time activities (consequence).

Under an operant model of behavioral psychology, the contingent delivery or removal of a consequence is seen as controlling or causing future behaviors. Whether a contingency represents reinforcement or punishment depends upon its effect, not desired effect, on future behavior. Reinforcement contingencies increase the probability of a behavior reoccurring under similar conditions and punishment decreases the probability of behaviors reoccurring. These procedures have utility for the school setting because teachers and other educators can often control the consequent conditions within educational environments and, thus, can often manage students' behavior by managing these contingencies.

806

BEST PRACTICES: INDIVIDUAL CONTINGENCIES

With individual contingencies, each component of the contingency can be adjusted to meet the target student's idiosyncratic needs, goals, and learning history. For example, a contingency could be established where Ralph is allowed to erase the blackboard (consequent) only when he maintains a neat workspace (behavior). This flexibility in adjusting contingencies for particular students serves as both a strength and weakness of individual contingencies.

Target Behaviors

One strength of individual contingencies is that educators can target uncommon and highly idiosyncratic behaviors that are not typically addressed with traditional classroom rules. The majority of elementary school teachers are likely to have established contingencies (e.g., classroom rules) designed to prevent the occurrence of some predictable incidental behaviors such as students getting attention without raising their hands and being called on, staying in seat, following directions, stealing, and fighting. However, it is not uncommon for a student to enter the classroom with specific behaviors not covered under the rules (e.g., self-injurious behavior). In these cases, rather than alter the class rules, a teacher may merely design and implement an individual contingency management program.

Criteria for Reinforcement or Punishment

A second advantage of using individual contingencies is that teachers have the ability to alter criteria based on each student's current level of functioning, learning rate, and goals. While two students may have identical target behaviors to earn reinforcement, the criteria for one student may be set at a different level than the criteria for another student. For example, Jack, who typically fails to complete any work, could receive reinforcement if he completes 50% of his assignments. John, who already completes 70% of his assignments, may need to complete 90% of his assignments in order to receive access to reinforcement. Additionally, the criteria to earn reinforcement can be altered on an individual basis, depending on each student's learning rate (i.e., shaping). For example, the criteria for reinforcement may be increased significantly each week for Jane, based on her rapid behavior change or learning rate. However, similar changes in criteria may occur more gradually with Dick, who is putting forth strong effort but learning at a lower rate.

Idiosyncratic Consequences.

Some consequences serve as natural reinforcers without any prior learning (i.e., unconditioned reinforcers). However, many reinforcers are conditioned, and thus the effect of the contingent delivery of these consequences may differ across students. For example, teacher reprimands delivered to Joe contingent upon his failure to complete his assignment may serve as punishment. Thus, in the future Joe may be more likely to complete his assignments in order to escape or avoid the reprimands. However, with Carl, reprimands may serve as reinforcers, thereby increasing the probability of Carl's failing to complete his assignments.

In addition to the consequences themselves, procedures may need to be strengthened for some behaviors by delivering reinforcers more immediately or at higher rates. For example, a particular reinforcer may be effective in altering behavior X for Joe, but not behavior Y. Specifically, high effort behaviors may require stronger reinforcement procedures in order to be effective (Skinner, 1998). Additionally, behaviors that have a current or long history of being reinforced on variable and thin schedules may be more difficult to alter. For example, strong reinforcement may be needed to alter the disruptive behavior of Curly, the class clown, who has often been reinforced and continues to be reinforced by his classmates for these behaviors.

Contextual Concerns Associated With Individual Contingencies in Educational Settings

Individual contingencies are often used in special education environments where individual education plans are encouraged and supported. However, within general education environments there are several limitations associated with individual contingencies.

One of the primary disadvantages is the time and resources required to develop and implement multiple individual contingency programs. Educators must identify target behaviors, criteria, and consequences for each student when developing individual contingency programs. After each component of the contingency is developed and implemented, educators should measure the target behavior regularly to determine if the procedure is being effective. Based on treatment monitoring data, educators can then adjust the contingency components (e.g., redefine target behaviors; alter criteria; and change reinforcement procedures including the reinforcer itself, the rate of reinforcement, and/or the immediacy of reinforcement) in order to maximize gains and program for generalization and maintenance of behaviors. When working with large groups of students, it is extremely difficult for educators to develop, consistently implement, evaluate, and alter distinct contingencies (e.g., distinct target behaviors, criteria, and consequences) across students and target behaviors.

A related problem associated with individual contingencies is the perception of "fairness." On the surface, perceptions of fairness may appear to be a rather insignificant characteristic of psycho-educational programs. However, students (i.e., "Jack is the teacher's pet.") and parents (i.e., "They are picking on my child.") may all respond negatively to programs that they consider unfair. These perceptions can hinder the development of professional relationships between educators and students and educators and parents (Henington & Skinner, 1998).

Educators also may be concerned over how the individual reinforcement programs affect the behavior of classmates. For example, suppose a class is going smoothly and most of the students are responding well to formal (e.g., classroom rules and grades) and informal (e.g., teacher managing her attention) contingency management programs. However, the teacher has two primary concerns: Jane is not turning in her homework, and John is not following directions. In these instances, the formal and informal procedures are not working. It may be that the consequences are not reinforcing and/or punishing to these students. Perhaps the rate, quality, and/or immediacy of consequences are insufficient to alter these behaviors. In this situation, individual reinforcement contingencies could be developed for John and Jane. However, in addition to concerns that students will complain about the teacher being unfair, there is also some concern that some of the other students may start exhibiting problems so they, too, can have the opportunity to earn extra reinforcement. No educators want to be responsible for causing well-behaved students to misbehave or for encouraging students for thinking that they must be squeaky wheels in order to get the grease.

Some Solutions to Concerns

In the above scenario there are several options. One option would be to develop individual punishment programs that target these specific behaviors of these two students (i.e., John's failure to follow directions and Jane's failure to complete homework). While classmates may demand the same opportunities to earn enhanced reinforcement as misbehaving students, they are less likely to demand opportunities to receive additional punishment. Thus, using additional punishment as opposed to strengthening reinforcement may solve the problems associated with perceived fairness. However, for some children, schools are aversive environments where their behaviors are rarely reinforced and often punished. In these situations, adding additional aversive stimuli to the educational environment can exacerbate problems. Additionally, many teachers may feel that they are already spending too much time reacting to and punishing inappropriate behavior, as opposed to encouraging, teaching, shaping, or rewarding desired behaviors. Finally, additional individual punishment programs may draw classmates' attention to students' inappropriate behavior and indirectly encourage them to ridicule, to be ostracized, or to socially reject students who are not performing well. Thus, it is not surprising that teachers may be reluctant to introduce aversive procedures designed to reduce inappropriate behaviors in specific students. Instead, most educators would prefer to reinforce and strengthen appropriate behavior (Elliott, Witt, & Kratochwill, 1991).

A second option would be to try to keep classmates unaware of enhanced reinforcement programs. For example, a teacher could whisper words of praise to a student for working hard. Another procedure would involve the student's parents, perhaps through the process of conjoint behavioral consultation (Sheridan & Kratochwill, 1992). For example, individual contingencies contracts for each student could be developed in conjunction with each student's parent (see Kelly, 1990). The advantage to such a system

808

is that parents could deliver additional reinforcement at home based on the student's behavior at school. Such systems may allow teachers to keep the student's classmates ignorant of the additional reinforcement programs and reduce classmates' objections with respect to fairness.

Peer-tutoring, self-management, and various other procedures also may be effective procedures for preventing and remedying individual student problems. Problem behavior can also be addressed by altering instructional procedures and assignments. Additionally, educators may find that adding or manipulating group contingencies allows them to prevent and remedy student problems in an efficient manner for both individual student and class-wide behavior management.

BEST PRACTICES: GROUP CONTINGENCIES

In addition to individual contingencies, there are three types of group-oriented contingencies: independent, interdependent, and dependent (Litow & Pumroy, 1975). Each type of group contingency contains the same components as individual contingencies. They include target student (e.g., Johnny), target behaviors and conditions (e.g., aggressive behavior during recess), criteria (e.g., under two times during the week), and consequences based on behaviors meeting specified criteria (e.g., opportunity to play computer game for 10 minutes). However, with group-oriented contingencies, one or more aspects of the contingency are associated with groups of students, as opposed to individual students.

Independent Group-Oriented Contingencies

Independent group-oriented contingency programs are often used to manage the behavior of groups. The term "group" typically denotes that the target behaviors, criteria, and consequences are the same across all members of the group. However, as the term independent denotes, each student receives access to the consequence based on his or her own behavior.

Independent group-oriented contingencies can be found across all levels of educational environments. For example, school districts or schools may establish punishment programs where any student engaging in a specific behavior (e.g., violating dress code) receives the same consequence (e.g., in-school suspension). Many classroom teachers establish their own independent group punishment programs designed to reduce the probability of students engaging in incidental inappropriate behaviors within their classrooms. For example, teachers commonly develop and teach their students classroom rules that identify inappropriate behaviors and the consequences for performing those behaviors (e.g., students who write on their desk will have to clean all the desks).

In addition to procedures designed to prevent inappropriate behaviors, educators also establish independent group reinforcement procedures designed to increase the probabilities of students engaging in appropriate behaviors. At the district and school level, awards are sometimes given for students for perfect attendance or obtaining consistently high letter grades (e.g., honor role or Dean's list). Within individual classrooms, teachers may establish token economies or merit systems where students earn exchangeable reinforcers (merits or tokens).

Because all students receive the same consequences for similar behaviors, independent group contingencies may be easier for educators to develop, teach to students, and consistently implement, rather than manipulating individual contingencies with distinct target behaviors, criteria, and consequences (reinforcers and punishers) for each student. Furthermore, when procedures are held constant across students and classrooms, it is easier for several education professionals to learn and implement independent group contingencies across environments (e.g., different classrooms). For example, a physical education teacher and a mathematics teacher could follow the same school-based procedures for each high school student who is late for class. Finally, when independent contingencies are implemented consistently, students, parents, and educational professionals consider these contingencies to be fairer than individual contingencies. Thus, independent punishment or reinforcement programs may be more acceptable to educators, parents, and teachers (Turco, Elliott, & Witt, 1985).

CONTEXTUAL LIMITATIONS AND SOLUTIONS ASSOCIATED WITH INTERDEPENDENT GROUP CONTINGENCIES

One of the primary strengths of independent group contingencies is that they can be used as part of proactive prevention programs designed to both increase (e.g., gold stars or letter grades of "A" for strong academic performance) or decrease student behaviors. However, there are some contextual concerns related to using independent group contingencies in educational settings. Many of these concerns are related to consequences and consequent delivery systems.

Reinforcers and Punishers Across Students. The same consequences are applied across students with independent group contingencies. In some instances, the same consequences may be reinforcing for Johnny but not for Jane and therefore have no effect on her behavior. On the other hand, a consequence that is punishing for Jane may actually be reinforcing for John. For example, being sent to the principal's office may serve as a strong punisher for Jane's acting-out behavior. However, the same consequence may strengthen Jack's acting-out behavior because it allows him to avoid doing academic assignments (i.e., negative reinforcement) or receive high rates of attention from the staff in the principal's office (i.e., positive reinforcement).

A related concern is the administration of particular reinforcers. Because some students receive access to reinforcers and others to do not, it is difficult to use activities as reinforcers. For example, teachers may want to use activities to reinforce students' appropriate behavior. However, it could be difficult for a teacher to take some students on a field trip, but not others, because teachers will have to develop other activities and find someone to monitor or teach students who did not meet criteria for earning the field trip (Skinner, Cashwell, & Dunn, 1996). Additionally, if the activities are educational it may be unethical (e.g., the students who do not meet the criteria may be most in need of the educational and motivation outcomes of the field trip), if not illegal (e.g., withholding educational opportunity from special needs students could violate their Individual Education Plan) to prevent students from participating in the activity. Finally, event or activity reinforcers are difficult to deliver to some students and not others (e.g., having a pizza party, taking a field trip). For these reasons, educators may have to rely almost solely on the use of tangible reinforcers when implementing interdependent reinforcement programs.

Reinforcer Belittling, Buying, Stealing, Forging, and Sharing. Administratively, it is relatively simple to deliver tangible reinforcers (e.g., tokens, gold stars, candy) to some students and not others. However, what happens after these reinforcers are delivered can cause problems. First, students who do not earn reinforcers may publicly belittle the reinforcers (e.g., "Lollipops are for babies."). Belittling may reduce the quality of the reinforcer for other students in the classroom. Reinforcers may also lose value for some students when students who do not earn reinforcers are able to purchase them independently. For example, in one classroom where a token economy was being run, a particular student spent 2 months earning tokens so that he could purchase a fancy multicolored pen. The day after he earned his final token and obtained the pen, a peer came to the class with the same pen that a relative had purchased for him at a local school supply store. This process appeared to reduce the reinforcing value of the pen for the student who earned it. An additional concern is if students can obtain reinforcers by performing alternative low effort behaviors (e.g., asking Aunt Joan for the pen), as opposed to having to meet classroom based performance criteria (e.g., earning 200 tokens), then the contingency is less likely to alter desired behavior (Skinner, 1998).

There are also several other ways to obtain tangible reinforcers without performing desired behaviors. One way is to steal or extort reinforcers from students who have earned them. Some students may also forge tokens or alter merit and demerit logs. In addition, an often-overlooked way in which students may obtain reinforcers is by sharing. Even though sharing may be an incidental prosocial behavior, it undermines the effectiveness of the program because students may receive reinforcers without meeting criteria. One way to address this issue is to implement punishment programs designed to decrease the probability of students stealing or forging reinforcers. However, educators generally encourage students to share with their peers; thus, attempting to discourage sharing may send students mixed messages regarding prosocial behaviors (Skinner, Skinner, Skinner, & Cashwell, 1999).

Same Target Behaviors and Criteria Across Students. Another concern is related to criteria set within the independent group contingency. It is often difficult

810

for educators to set criteria that encourage all students to perform at their best, or optimal, level or academic or behavioral performance. For example, an 80% criteria to earn reinforcement may be too low for Jill who regularly makes a 95% on her spelling test. In this instance, it is possible that Jill may reduce the amount of time and effort spent studying, make lower grades, but still meet the criteria to earn reinforcement. This decrease in performance is less likely to happen when other contingencies yield reinforcement for the high scores (e.g., 95% yields better grades than 85%). The disadvantage with one criterion for all students may have a more detrimental effect on Jack who typically makes a 40% on spelling tests. When criteria to earn reinforcers are set too high, students may give up rather than attempt to reach the goal.

Public Performance Feedback and Interactions of Identical Reinforcement and Criteria. As with individual reinforcement programs, the public nature of independent group contingency programs can have an aversive impact on student relations. Because each student's behavior is reinforced or punished based on the same target behaviors and criteria, peers can determine who met the criteria if they know whether or not students receive access to reinforcers or punishers. Thus, a certain level of public feedback regarding each student's behavior accompanies public delivery of consequences. For example, a teacher may pass out tangible reinforcers (e.g., erasers) to each student who earned 90% or higher on an exam and require those who made less than 70% to complete a remedial in-seat assignment. In both cases, the consequent delivery system provides the students with information regarding their peers' performance. Many teachers avoid publicly posting each student's exam performance because it may encourage classmates to ridicule or ostracize peers who did poorly (Cashwell, Skinner, Dunn, & Lewis, 1998).

SOME SOLUTIONS TO CONCERNS

As previously discussed, it is not always easy to identify consequences that are resource efficient (e.g., activities that take little teacher and student time or cost little money) and reinforcing across students. However, educators have several options. For example, token economies can be established in which students earn reinforcers (i.e., tokens) that can be exchanged for a variety of other reinforcers. Another solution is to allow students to randomly select reinforcers, (e.g., a grab bag) based upon meeting some specific criterion (Rhodes, Jenson, & Reavis, 1993). Such procedures are more likely to be effective across students as long as some of the consequences in the pool are reinforcing to each student. Additionally, research suggests that randomly selecting reinforcers or using unknown reinforcers may result in greater behavior change than using known reinforcers (Moore, Waguespack, Wickstrom, Witt, & Gaydos, 1994).

If reinforcers are randomly selected, then it may be appropriate to include some neutral stimuli. For example, in one seventh-grade classroom after a student met the criteria they were allowed to draw a wrapped prize from a treasure chest. The treasure chest included some high quality reinforcers (e.g., token for a soft drink, candy, multi-colored pens). Additionally, the teacher included some gag prizes that could be randomly selected such as an autographed picture of himself, an empty envelope, and a sticker of a Smurf ™. The key to these silly, neutral consequent stimuli is that they may prevent some students from focusing on or ridiculing those who did not earn reinforcers.

Although randomly selecting reinforcers may prove extremely useful, it is not advisable to use the same strategy with aversive consequences. Random selection of aversive consequences is considered unfair and potentially unethical. In addition, random application of aversive consequences will likely raise concern of parents, students, and others concerned with due process issues. Thus, when using punishment, educators should be consistent and inform students before they are punished of specific behaviors and criteria that will lead to punishment and exactly what that punishment will be (e.g., teach classroom rules and specify aversive consequences for breaking the rules before students engage in inappropriate behaviors).

It is more desirable to alter and manage student behavior by implementing reinforcement programs; however, some schools may only implement independent group contingencies designed to punish inappropriate behavior. When employing punishment procedures within independent group contingencies, educators and/or consultants should ensure that punishers are aversive to all students. If consequences are neutral, then these consequences are likely to have little effect on target behaviors. When consequences intended to act as punishers are reinforcing (e.g., for some students being yelled at may serve as a reinforcing event), then the independent group contingency may actually increase inappropriate behaviors for some or all students. Because independent group punishment programs are sometimes ineffective, educational systems often have procedures or mechanisms that lead to alternative or individual programs. For example, a student who is caught destroying school property may initially receive in-school suspension. A second offense may yield longer in-school suspension, and a third offense may result in a parent-educator conference where individual contingencies are structured that allow for the development of distinct aversive consequences that may be more effective in reducing inappropriate behaviors. Thus, when the more efficient independent group punishment programs fail, school systems invest the time and resources needed to develop individual punishment programs.

Interdependent Group Contingencies

With interdependent group contingencies, every member of the group (e.g., entire class) receives access to the same consequence based on some aspect of the group's behavior (e.g., a class average on a test, no more than three unexcused absences for the class in a month). Thus, consequences are delivered to all (or none) of the students. Interdependent group contingencies are typically used in cooperative learning programs (Slavin, 1987) and class-wide peer tutoring (Greenwood, Terry, Arreaga-Mayer, Finney, 1992). Additionally, these contingencies have often been used to prevent incidental antisocial behaviors and enhance prosocial behaviors (Kelshaw-Levering, Sterling-Turner, Henry, & Skinner, 2000; Skinner, Cashwell, & Skinner, 2000).

There are several applied advantages associated with interdependent group contingencies. Because all or none of the students receive access to consequences, it is much easier to deliver reinforcers when the group meets their goal (Gresham & Gresham, 1982). It is much easier to pass out reinforcers to everyone as opposed to checking each student's performance and only giving reinforcers to those who met criteria. Furthermore, because every student receives access to these reinforcers, the probability of students stealing or sharing tangible reinforcers may be reduced. Finally, activity reinforcers such as listening to music during independent seat-work, taking educational field trips, and having the principal kissing a pig are much easier to deliver to the entire group (Skinner, Skinner, Skinner, and Cashwell, 1999).

With individual or independent group reinforcement, students are not affected by their peers' performance. However, with interdependent group reinforcement, the probability of the group gaining access to reinforcement is enhanced when peers meet criteria. Thus, interdependent group contingencies may result in diverse groups of students cooperating (e.g., encourage one another) to achieve a common goal. For example, a student may tutor peers in order to increase the group's average on an exam, or students may remind one another to take their mathematics homework with them as they prepare to leave for home.

CONCERNS

Interdependent group contingencies are efficient procedures that can be used to encourage students to work together in order to meet group goals. However, there are several limitations associated with using these contingencies with educational environments.

Consequences. Interdependent group contingencies are rated as less fair than independent group contingencies (Turco & Elliott, 1990). However, this perception may be of more concern with interdependent group punishment as opposed to interdependent group reinforcement procedures. Individual students may respond negatively when they perform well, but do not earn a reinforcer because other students performed poorly. However, students are likely to consider it even more unfair and raise stronger more forceful objections when they perform well, but are punished based on their classmates' behavior. For example, students may aggress against poorly performing peers or teachers (Barrish, Saunders, & Wolf, 1969).

Parents, students, and other educators also may object to using academic grades as consequences contingent upon some aspect of the group's behavior. Students' academic grades should be based on their own learning, not their peers' performance. Therefore, academic grades should not be the primary consequences when employing these contingencies. Instead, these contingencies can be used as additional motivation to traditional grading procedures (see Shapiro & Goldberg, 1986, for an excellent example).

Another concern with interdependent group contingencies is related to reinforcer effects across students. If a consequence that is designed to reinforce the group is actually aversive to a group member, then that group member could engage in behavior designed to prevent the group from earning access to reinforcement. For example, suppose the reinforcer was the opportunity to go to a planetarium and a particular student hated the planetarium. This student could be negatively reinforced for engaging in behavior designed to sabotage the possibility of the group meeting their collective goal (Hayes, 1976).

Target Behaviors. Although interdependent group contingencies can be used to increase desired behaviors and decrease inappropriate behaviors, educators should exercise caution when target behaviors are social and public. Research suggests that students may be more likely to threaten classmates with aversive consequences and apply those consequences to prevent peers from engaging in public inappropriate social behaviors (Pigott & Heggie, 1985). It should not be surprising that students would employ such aversive strategies as educators and other adults often establish and implement independent group punishment procedures (e.g., classroom rules) to prevent and alter incidental inappropriate behaviors.

Criteria and Feedback. With individual and independent group contingencies, failure to set criteria appropriately for each student can result in inappropriate reactions with individual students (e.g., giving up when the criteria are set too high or lowering performance to meet expectations that are too low). Because interdependent group contingencies affect an entire class, extra care must be taken when establishing criteria. If criteria are set in a manner where students lose the opportunity to earn reinforcers early, then they may no longer attempt to alter target behaviors or meet performance expectations. For example, suppose an interdependent group contingency is established where the group will receive access to reinforcement if all students arrive on time to class for an entire week. If Steve arrives late on Monday, then the entire class may stop trying to arrive to class on time for the remainder of the week because it is no longer possible to earn the reinforcer. Additionally, because this is a public behavior, this student's classmates may socially or physically punish him for this behavior.

Solutions to Concerns

Randomizing interdependent group contingency components may help prevent many problems associated with interdependent group contingencies (Skinner et al., 1996). Randomly selecting reinforcers from a pool of reinforcers is likely to prevent sabotage because some consequences in the pool are likely to be reinforcing for each student. Having students participate in the development of the reinforcers pool by suggesting reinforcers may also increase their commitment to the contingency plan. Additionally, providing a mechanism for students to periodically add to or alter the pool of reinforcers may help maintain their enthusiasm for the program.

It is fairly easy for teachers and students to develop a variety of reinforcers. Furthermore, because all or none of the students receive access to reinforcement, a variety of reinforcer options including activities can be used (Skinner et al., 1999). Activities often serve as excellent reinforcers because they can be resource efficient (e.g., listening to music during independent seat work, the principal kissing a pig). Additionally, randomly selected or mystery reinforcers may be more effective for changing behaviors (Moore et al., 1994; Rhodes et al., 1993).

Problems associated with students failing to meet criteria can also be addressed through randomization. For example, rather than specifying the criterion (no more than three instances of students failing to turn in homework for the entire week), educators could merely specify the target behavior (homework) and at the end of the week they could randomly select the exact criterion (Kelshaw-Levering et al., 2000). The teacher could have slips of paper with 3, 5, 7, 9, 11, 13, 15, etc., within a criteria pool, representing the number of homework assignments turned in. Therefore, if several students forgot their homework on Monday, the class could still earn the reinforcers if the teacher were to randomly select a lower number at the end of the week.

When random criteria are combined with random reinforcers, students may become upset and engage in inappropriate behaviors when they learn about reinforcers they could have obtained if they met the criteria. Furthermore, if the reinforcer they failed to earn is extremely powerful, students may be more likely to attempt to identify and punish group members who performed poorly. Thus, it is advisable to first select the criteria, and then only select the reinforcer when they meet the criteria (Skinner et al., 1996).

Another solution to the problems related to group criteria is to use cumulative criteria (see Skinner et al., 2000). For example, the class could earn access to group reinforcement when they turned in 100 homework assignments at 85% or higher accuracy. Thus, every instance of complete, accurate homework would bring the group closer to earning reinforcement. One teacher who used this procedure reported that the students began asking for more homework assignments. In another example, Skinner et al. (2000) reinforced students for cumulative reports of peers' incidental prosocial behavior. Thus, any incidental prosocial behavior displayed by any student and reported by any peer helped the class meet their group goal.

Within educational settings that primarily employ independent group contingencies for academic performance (e.g., grades) and inappropriate behavior (e.g., classroom rules), there are some students who rarely perform well enough to earn reinforcers. Using cumulative criteria may provide these students with the opportunity to contribute to the group earning the reinforcement and to receive access to reinforcers. Cumulative criteria may also improve the behavior and performance of these students and enhance their self-concept and attitude toward education environments (Cashwell et al., 1998).

There are some target behaviors or tasks that are, by nature, more interdependent in that they require students to cooperate. For example, many team sports and extra-curricula activities (e.g., band, cheerleading) require students to work together in order to achieve their goals. Within graduate education, school psychology programs often form research groups where the success of the group is dependent upon all members doing their part. Within general education environments, a variety of cooperative learning activities have been developed that also incorporate interdependent tasks with interdependent group contingencies. (See Kagan (1985) for an excellent summary of several cooperative learning procedures.) Thus, general education professionals can structure more cooperative tasks or assignments and use these contingencies to reinforce students.

Interdependent group reinforcement procedures encourage diverse students to work together to meet common goals. Thus, these contingencies may be most appropriate for enhancing and encouraging incidental prosocial or cooperative behaviors within educational settings. For example, group contingencies may help address generalization concerns associated with social skills. Although social skills training programs are effective in teaching students prosocial behaviors, students may not engage in these prosocial behaviors in their natural environments after they have been learned (DuPaul & Ekert, 1994). Interdependent group contingencies that target specific prosocial behavior during the school day could prove to be effective mechanism for programming for this generalization (Gresham, 1995).

Interdependent group contingencies that target incidental prosocial behaviors may also decrease incidental anti-social behaviors. For example, suppose Cindy walks into a room and drops a pile of books. Classmates could (a) ignore Cindy, (b) engage in antisocial behaviors such as ridiculing Cindy or kicking the books, or (c) engage in prosocial behaviors such as helping Cindy pick up the books. Often educators establish and implement independent punishment procedures (classroom rules) designed to prevent students from engaging in the antisocial behaviors (e.g., kicking Cindy's book or calling her a dork). To avoid punishment, students could do nothing (e.g., ignore Cindy). However, within educational environments proactive procedures should be designed to support and encourage incidental prosocial behaviors, as opposed to merely punishing inappropriate behaviors. Skinner et al. (2000) developed an interdependent group reinforcement procedure where the entire class received access to reinforcement contingent upon incidental prosocial behaviors. With this type of system, the natural classroom environment is altered so that all members of the group are more likely to receive access to reinforcers when they engage in high rates of day-to-day incidental prosocial behaviors.

Dependent Group Contingencies

Dependent group-oriented contingencies are similar to interdependent group contingencies, in that all or no member of the group receives access to the same

814

consequence. However, with dependent group contingencies, access to consequences is based on the behavior or performance of one or several students.

From an applied perspective, there are several advantages associated with dependent group contingencies. First, educators are often only concerned with the behavior of one or a few students (e.g., Dick and Jane). With dependent group contingencies, educators are only required to take data on these behaviors, as opposed to the behavior of the entire group. A second advantage is that when these programs are in place, all students receive access to reinforcement when these students meet criteria. Thus, classmates may be less concerned about misbehaving students receiving extra reinforcement. Another strength of this procedure is that it can allow students who are socially neglected or rejected to gain some positive attention from their peers. For example, a teacher may reinforce the entire class contingent upon Johnny's meeting a specific goal.

LIMITATIONS AND SOLUTIONS FOR DEPENDENT GROUP CONTINGENCIES

There are many limitations associated with dependent group contingencies. The primary concern with these contingencies is how classmates will respond to target students. Because access to consequences is based on their peers' behavior, classmates may engage in undesirable behaviors in an attempt to influence their peers' behavior. For example, students may threaten target students or ridicule and ostracize them if they fail to meet the criteria to earn reinforcement or avoid punishment (Romeo, 1998). Therefore, care must be taken when implementing these contingencies.

Although dependent group contingencies are rarely used in educational settings, they have been employed in extra-curricula activities at times. For example, a coach may require the entire team to run additional laps because a teammate did not perform well during drills. While this punishment may decrease the probability of future inappropriate behaviors, it may also result in peers providing additional social and, perhaps, even physical punishment. Obviously, educators should not establish programs that indirectly encourage peers to punish each other. Additionally, peers often consider such programs so unfair and unjust (being punished for someone else's behavior) that they may avoid environments where such programs are implemented. For these reasons, dependent group punishment should not be used in educational settings.

With dependent group reinforcement programs, a specific student's performance can result in the entire class being reinforced. Again, students who are performing well often consider these programs unfair when they do not receive access to the rewards. Additionally, even with reward programs, peers may apply inappropriate pressure or threats of aversive consequences to target students.

However, dependent group reinforcement procedures can be employed in a manner that may alter students' behavior without causing negative side effects. One solution is to use random procedures when selecting target students (Gresham & Gresham, 1982). For example, a teacher may establish a contingency where the entire class receives access to reinforcement if a randomly selected student makes 90% or higher on an exam. Because exam grades are not made public, the teacher could randomly select a student's name, check the one score only, and then inform the class if they will receive access to the reinforcers. The key here is that if the randomly selected student did not meet the criteria, then the teacher would not announce the student's name. However, if the student did meet the criteria, then the teacher could announce the student's name. This process may actually encourage peers to socially praise the student who performed well, as opposed to socially and perhaps physically punishing the student who performed poorly. In fact, one teacher set high criteria on a history test for an entire class of seriously emotionally disturbed students to receive a group reward (Skinner & Watson, 1995). The only student who consistently met these high criteria was a quiet child who displayed poor social skills and was often rejected or neglected by his classmates. Thus, when it came time to draw the name, the entire class was chanting the neglected student's name. When it was drawn and announced, the student received a burst of verbal and physical praise and encouragement (high fives all around) from his peers. Such positive interactions with peers were rare for this student.

SUMMARY

Group contingency management procedures have been extremely effective for altering student behaviors. A meta-analysis examining the impact of interventions on students' disruptive classroom behaviors showed that group contingencies yield greater effect sizes than any other interventions reviewed (Stage & Quiroz, 1997). Additionally, because group contingencies are designed for use across groups of people, they can easily be assimilated into educational environments. However, contingency management programs are similar to other effective intervention and prevention procedures in that inappropriate application of these programs can have a negative impact on classroom environments (e.g., encourage students to punish peers, make students feel that they are being treated unfairly or unjustly).

Unfortunately, many psychologists, educators, and researchers have focused on the undesirable side effects associated with the inappropriate application of behavioral procedures in general and, more specifically, group contingencies. For example, Romeo (1998) discouraged the use of group contingencies in classroom settings but (a) failed to differentiate between the different types of group contingencies, (b) suggested that all group contingencies cause negative side effects because they cause students to socially punish peers, (c) provided no analysis of procedures that can be used to mitigate negative side effects when using various group contingency procedures, and (d) neglected to discuss and analyze any of the positive side effects associated with these contingencies (e.g., students who rarely earn reinforcement gaining access to reinforcers, encouraging diverse students to interact in a positive goal-directed manner).

School psychologists are committed to the practical, efficient, and effective procedures that can prevent student learning and behavior problems. The current chapter provides a balanced analysis of group contingencies and specific recommendations for implementing these procedures in educational environments. This information should make readers aware of the many different modifications that can be made to various contingency management programs that can (a) mitigate negative side effects associated with contingency management procedures, (b) enhance the effectiveness of contingency management programs in preventing or remedying target behaviors, and (c) also enhance positive side effects associated with contingency management programs. This information should allow school psychologists to design and consult with educators (e.g., teachers and administrators) to develop and implement more effective and efficient contingency management programs within the context of educational environments.

ANNOTATED BIBLIOGRAPHY

Kelshaw-Levering, K., Sterling-Turner, H. E., Henry, J. R., & Skinner, C. H. (2000). Randomized interdependent group contingencies: Group reinforcement with a twist. *Psychology in the Schools, 37*, 523–533.
This databased intervention article provides a good example of how randomized contingency components can be applied within educational settings to reduce disruptive behaviors while minimizing the probability of negative side effects. This article serves as an excellent model for researchers interested in studying the impact of randomized group contingencies.

Litow, L., & Pumroy, D. K. (1975). A brief review of classroom group oriented contingencies. *Journal of Applied Behavior Analysis, 8*, 431–347.
This brief expository article provides an excellent overview of group contingency procedures with a focus on classroom applications. A particular strength of this article is the manner in which contingencies are defined.

Shapiro, E. S., & Goldberg, R. (1986). A comparison of group contingencies for increasing spelling performance among sixth grade students. *School Psychology Review, 15*, 546–557.
This databased article compares the impact of various group contingencies on academic performance. The methods section provides excellent guidance for how different group contingencies can be implemented with educational settings to promote academic performance.

Skinner, C. H., Cashwell, C. S., & Dunn, M. S. (1996). Independent and interdependent group contingencies: Smoothing the rough waters. *Special Services in the Schools, 12*, 61–78.
This expository article focuses on applied strengths and limitations associated with interdependent group oriented contingencies with a focus on using randomized contingency components to address limitations. Those who are consulting with special education and general education teachers may find this a valuable resource.

Skinner, C. H., Cashwell, T. H., & Skinner, A. L. (2000). Increasing tootling: The effects of a peer-monitored group contingency program on students' reports of peers' prosocial behavior. *Psychology in the Schools, 37*, 263–270.
This databased program shows how interdependent group contingencies can be applied within in elementary school classrooms. This study provides an excellent example of using interdependent group contingencies to encourage and support incidental appropriate social behaviors.

53 Best Practices in Teaching Study Skills

Virginia Harvey
University of Massachusetts, Boston

OVERVIEW

Study skills can be taught to students of all ages and abilities and, when practiced and monitored by the student, make a substantial difference in student achievement (Hattie, Biggs, & Purdie, 1996). Students who organize their time well, have good test-taking skills, and identify and learn main ideas are able to achieve higher grades and perform at higher levels on standardized tests even when diagnosed as behavioral disordered (Foley & Epstein, 1992). Often instruction in study skills is neglected because it is assumed that students learn these skills on their own, have mastered them at an earlier level (Devine, 1987), and know enough about their own learning to be able to generalize strategies across academic domains. Unfortunately, these assumptions are often unfounded.

According to Hattie, Biggs, and Purdie (1996), study skills interventions can focus on *affective considerations* (motivation and locus of control), *metacognition* (planning and monitoring learning), and *cognitive strategies* (specific strategies). When students do not have the affect, metacognition, and cognitive strategies necessary to be good students, a large proportion are referred to school psychologists. Interventions to improve study skills can often take place in prevention or pre-referral programs, thereby preventing the need for extensive assessment and restrictive placement.

BASIC CONSIDERATIONS

Studying is deliberate and purposeful learning that is pursued autonomously. It is therefore important to consider the ability to self-organize and self-evaluate as well as use specific strategies (Gettinger & Nicaise, 1997; Hoover, 1990). Research has not consistently demonstrated one study technique as superior to others. Students with effective study habits use a variety of techniques and are able to articulate their reasons for choosing particular tactics for particular assignments (Wade, Trathen, & Shaw, 1990). Students should be taught various tactics and methods to monitor success.

The most important consideration in improving study skills is to incorporate fundamental principles of effective learning into studying. Learning requires the ability to focus on important information, tie new information to previously learned material, space and repeat trials, involve multiple senses, incorporate corrective feedback, monitor learning, and take steps to increase comprehension. There are multiple methods available for incorporating these principles described in this chapter. Increasing focus on important information can be accomplished by outlining, taking notes, mapping constructs, pre-reading, or modifying reading strategies. Tying new information to previously learned material can be accomplished by linking or mnemonics. Spacing and repeating trials can be accomplished with the SQ3 method in reading or the use of the Cornell method in note taking. Methods to incorporate corrective feedback include collaborative learning, reviewing corrected homework and tests, interactive videodisk instruction, or the writing process.

Students should not be expected to use all of these methods for every subject, as that would be needlessly time consuming. The number of study skill strategies used has not been found to correlate with achievement (Foley & Epstein, 1992), and students are very unlikely to use every type of study skill (Slate, Jones, & Dawson, 1993; Stanley, Slate, & Jones, 1999). Effective study strategies include the abilities "to plan and control, to think and inquire, and to reflect and self-evaluate" (Gettinger & Nicaise, 1997). The school psychologist's role is to help determine which learning principles are being neglected and to help teachers and student(s) select the most helpful strategies from a menu of methods. Appropriate strategies will vary according to the student's style of learning and personal habits, the subject matter, and the teacher's approaches.

School psychologists' training facilitates their work in assessing and improving students' study skills. Integral to work in this area is knowledge of human learning and memory, skill in assessing individual differences and applying curriculum-based assessment, knowledge of learning styles, skill in consulting with parents and teachers, expertise in ecological assessment, an understanding of the importance of metacognition, knowledge of factors resulting in increased treatment adherence, and knowledge of the scope and sequence of instruction in all subject areas. In addition, school psychologists need knowledge and skills in direct interventions including co-teaching, behavior management plan implemen- tation, anxiety reduction strategies such as progressive relaxation exercises, basic counseling strategies, and skill in providing in-service training to teachers.

BEST PRACTICES

Assessing and improving a student's ability and desire to manage work and time effectively through the improvement of study skills can be one of a school psychologist's most effective interventions. Best practice includes collaborating with regular educators to teach study skills in conjunction with established curriculum (Langer & Neal, 1987; Slate, Jones, & Dawson, 1993). Teaching study skills in conjunction with a social studies curriculum and leading teacher seminars on study skill improvement raised student exam scores from the failing to the honor roll range (Leland-Jones, 1997). Individually meeting with students to review their cumulative files (grades, tests scores, and attendance), helping students develop learning goals, providing in-service workshops on improving study skills, and teaching study skills in the regular classroom resulted in a three-grade equivalent improvement on standardized test scores in one year (Carns & Carns, 1991). If taught in isolation, study skills are unlikely to be maintained or to transfer from one setting to another. Therefore, effective remediation requires that the school psychologist, teacher, and parent work closely together to determine appropriate procedures, designate responsibilities, and design techniques to encourage generalization.

Assessment of Existing Study Skills

Study skills should be assessed whenever the referral question concerns academic effort or behavior. Formal instruments for assessing study skills exist (Pintrick, Smith, Garcia, & McKeachie, 1991; Weinstein & Palmer, 1990), and some are available in a computerized format (Tait & Entwistle, 1996). However, these have been criticized for ignoring the essential component of metacognition (Kiewra, 1996). Given that there is not a reliable tool to cover the broad band of critical issues, the most productive method is ecological assessment that investigates in several domains. There are five basic steps:

1. Interview the teacher and parent during a prereferral conference, using the Study Skills Assessment Checklist (Table 1) to determine general areas of weakness.

2. Observe the student in class and analyze work samples to obtain further information. Selectively use the Checklist of Classroom Qualities that Foster Study Skills (Table 2) during the observation.

3. Interview the student. Selectively use questions from the Study Skills Assessment Checklist and the Student Interview Questions (Table 3). Observe carefully while the student completes academic work in your presence. Have the student describe work methods, approaches to studying, and weekly schedule. Have the student show and describe textbooks, notebooks, assignment books, and completed work. Assess the affect and metacognition (see below).

820

Table 1. Study skills assessment checklist

Affective considerations

- Does the student understand that he or she has some control over his or her life and academic achievement?
- Is lack of motivation a concern? Is the purpose of learning the material understood?
- Does the student have learning goals?
- Is the student motivated to use study skills?
- What kind of homework does the student enjoy? Dislike? Why?
- What does the student like about the way he or she handles homework? Dislike?
- Does the student suffer from disabling academic anxiety?

Metacognition

- Does the student have metacognitive skills that enable him or her to assess his or her own level of knowledge?
- Does the student consider the type of reading material in planning how to approach a reading assignment?
- Does the student plan for learning? For example, are all materials necessary for homework completion brought home? Are sufficient supplies available?
- Does the student estimate how long it will take to complete an assignment? Is this time estimate used to make a daily schedule? Is the schedule followed?
- Are short-term assignments kept track of in a book or log? Are long-term assignments, tests, reports, and projects kept track of in a calendar?
- Does the parent regularly check the assignment calendar/homework sheet with the child, as well as checking for notices, permission slips, and other school communication?
- Does the teacher regularly check the assignment calendar/homework sheet and monitor homework completion?
- Does the teacher make expected study strategies explicit, discuss recommended approaches regularly in class, and convey to students that he cares about and desires their success?
- Is there a regular, quiet time to study at home?
- Is there adequate communication between the home and school to support homework completion?
- Is there adequate support at home to foster good study strategies?
- What does the student do when unable to understand something at home?
- Can the student asses his or her own preferred learning style to determine the best environment for studying, and then work with his or her family to obtain this enviroment? Where does the student prefer to do homework? Is there a place at home to study that is quiet and well lit, with a table or desk?

Cognitive strategies

Organization

- Are assignments turned in with a label, name, and date? Are they neat? Are they complete? Are assignments checked for errors, and corrected, before being turned in?
- Does the student (grade four and below) keep one folder for assignment sheets, with "work to do" on the left and "work to turn in" on the right?
- Does the student (grade five and above) keep a loose-leaf notebook or notebooks organized chronologically, by subject?
- Does the student come to class with notebook, pencil, completed homework, and textbook?
- Is the student's desk, cubby, or locker neat enough that the student can locate required materials quickly?

Listening skills

- Are directions understood?
- Are directions followed?
- Does the student listen in class?

Note-taking skills

- Are notes taken in class? Does each page of notes have the date and topic written at the top?
- Are details added to class notes as soon as possible after class?
- Is a note-taking system used?
- Are relevant reading materials pre-read before the lecture on the same material?

Reading skills

- Does the student pre-read?
- When there are words that the student does not understand in the reading, does the student determine their meaning and write them down?
- Is the student easily distracted or bored while reading?

(Table continues on the following page.)

Table 1. (continued)

- Are personal copies of textbooks available to the student? Does the student know how to take notes in textbooks by highlighting or making margin notations?
- Is a reading technique used when reading difficult assignments?
- Does the student outline or take notes from reading assignments?
- Does the student know how to "map" a reading?
- Does the student know how to summarize effectively?
- Does the student use headings and other typographical aids? Can the student read tables, charts, and graphs? Does the student know how to use the table of contents and index of a book?
- Is the student able to comprehend textbooks?
- Can the student predict outcomes, distinguish fact from opinion, discern emotional appeals, recognize bias, and discern inference?

Math and science skills

- Does the student work on math and science problems on a daily basis?
- Does the student employ an outline or use 3 x 5 flash cards to help learn and remember definitions, important ideas, key examples, and theorems?
- Does the student know how to use a scientific calculator? A graphing calculator?
- Does the student estimate the answer in conjunction with using a calculator?
- Does the student review problems already completed? Does the student try new problems that were not assigned?
- Does the student choose problems from a variety of sections to test understanding?
- Does the student participate in a study group?

Reporting skills

- Does the student know how to find information using books, maps, graphics, newspapers, dictionaries, libraries, the Internet, and other reference tools?
- Can the student use the computer catalogue in the library and then locate the material? Can the student use the periodical index?
- Does the student organize papers, by outlining or using a story map, before writing? Does the student write a first draft?
- Does the student proofread for success/failure in answering the purpose of the assignment, legibility, neatness, spelling, complete sentences, and punctuation errors?
- With which reporting techniques is a student familiar? Most capable? Which does he or she prefer?
- Is the student skilled in using word processing for assignment completion?

Test-taking habits

- Does the student space learning over several sessions (versus cramming) and use a study plan? Does the student conduct weekly reviews?
- Does the student study using the SQ3R (see Reading Study Skills) or a similar method?
- Does the student predict test questions?
- Does the student know and use good test-taking strategies?
- Does the student make use of study guides prepared by the teacher?

4. Determine appropriate intervention techniques. The most effective strategy is the incorporation of techniques into instruction, preferably for all students in a class. Several commercial materials are available as curriculum guides for classroom instruction in general study skills, some of which are listed in Table 4. Other possible intervention approaches include individual instruction, bibliotherapy, computer assisted instruction, the Internet, teacher consultation, teacher training, and/or district curriculum consultation. As was mentioned previously, the school psychologist's role is to help determine which learning principles are being neglected and to help teachers and student(s) select and implement the most helpful strategies from a menu of methods.

5. Develop a plan of maintenance and generalization for the interventions. The implementation of interventions requires ongoing monitoring until the behavior is used consistently (Table 5).

Affective Considerations

Does the Student Understand That He or She Has Some Control Over His or Her Academic Achievement? Students whose locus of control is primarily external will need to be led through successful expe-

Table 2. Checklist of classroom qualities that foster study skills

General	Tasks are stimulating and challenging.
	Students are treated as individuals with varied needs and talents.
	Regular successes are experienced by the students and displayed.
	The classroom is organized.
	The classroom has minimal distractions and is quiet for independent work.
	Expectations for students are clear.
	Students are not subjected to public humiliation or criticism.
	Before speaking, the teacher gains the attention of the class.
	Students are encouraged to self-evaluate their learning and study strategies.
	Students are encouraged to set learning goals.
Assignments	The teacher gives assignments both orally and in writing.
	Assignments are clear and work models are provided.
	The teacher checks that students write assignments in an assignment book.
	Homework assignments follow successful classroom practice.
	Worksheets have sufficient writing space and are dark enough to read.
	Work is collected, corrected, and returned promptly.
Lectures	Unfamiliar concepts are taught before lectures or readings.
	Students are taught to relate material to their own lives.
	Frequent examples are given in class.
	Visual aids are frequently used.
	Relevant material is distinguished from irrelevant material.
	The teacher frequently checks for students' understanding.
	To increase understanding, the teacher rephrases and simplifies.
Reading	Students are taught to recognize a speaker's or writer's purpose.
	Students are taught to note transitions in the talk or text.
	Students are taught to recognize main points, details, and sequence of ideas.
Math	Students are given review, current, and challenge problems.
	Students are encouraged to participate in collaborative learning groups.
Note-taking	Students are taught to take notes.
	Students are taught how to summarize.
	Students are taught how to draw conclusions and make inferences.
Tests	Tests are administered in a low-anxiety atmosphere.
	Students know test question formats and are given example test questions.
	Partially completed study guides are provided.
	The material to be covered on tests is clear to students.

riences to help them understand that the effort they expend relates to the outcome they experience, and that their success in school is not simply an effect of innate ability or luck. One method of linking personal success to effort can be to ask students "when" questions, such as (to a non-reader), "How old do you think you will be when you learn to read?" Another is to have each student track study activities and resultant success.

Is Lack Of Motivation A Concern? Is the Purpose of Learning the Material Understood? To increase motivation and the ability to comprehend material, students need to understand the purpose of the material, including why the teacher assigned the material and how the assignment relates to students' learning goals. Understanding the purpose of reading material also includes understanding the author's intentions and reading actively to answer questions. Similarly, students often need help bridging the information they are learning in math, science, and social studies to their lives. Group discussions, individual counseling, and discussions led by older students can be helpful in this regard.

Does the student have learning goals? These should be both general ("go to college") and specific

Table 3. Student interview questions

About you	1.	What do you like to do best?
	2.	What do you like to do least?
	3.	What do you do especially well? What are your strongest skills and abilities?
	4.	What do you do least well?
	5.	What are five jobs you might like to have as an adult?
	6.	What would you like to know, and know how to do, when finished school?
About school	7.	What are your favorite school activities?
	8.	What do you dislike most about school?
	9.	Why do you think you don't do well in school?
	10.	What are five skills you believe are important to succeed in school?
	11.	What grades do you want to get in school?
	12.	Looking at the grades, test scores, and attendance records in your cumulative file, do you see any patterns? How do you explain them?
	13.	What are your main academic goals for the next year? For the future?
About home	14.	What grades do your parents want you to get in school?
	15.	Do your parents praise you for your school work?
	16.	Where do you like to study? When?
	17.	How much sleep do you get each night?
	18.	What type of exercise do you get? How often?
	19.	What chores do you have at home?
	20.	Keep a log of your studying activities for a week, blocked off in half-hour units.

("obtain a score of 80% on tomorrow's test"). Having students write long and short-term goals for each subject, such as math, and converting them into weekly planners, including study strategies, can be a very effective intervention (Seon & King, 1997).

Is the Student Motivated to Use Study Skills? Rauch and Fillenworth (1995) asked students what motivated them to use, or discouraged them from using, new study strategies. They found that students often did not know how to apply strategies to particular classes, felt they would take too much time, and had difficulty integrating the new strategies into their study habits. Thus, study skills should be (a) related to particular courses and monitored, (b) associated with positive and responsive teacher-student relationships, and (c) incorporated into students' goals.

What Kind of Homework Does the Student Enjoy? Dislike? Why? Many students assume they dislike all types of homework when they actually do like some types (projects, perhaps). Knowing homework preferences helps in developing a homework schedule. Some students prefer to get the disliked homework done first, while others prefer to do their easier work first. Students can be made aware that when they dislike a subject they can find ways to make it less frustrating. For example, they might set themselves a goal of doing five math problems and then taking a stretch.

What Does the Student Like About the Way He Handles Homework? Dislike? Whatever students dislike about the way they handle homework can be subjected to a brainstorming session, and one of the solutions brainstormed can be chosen, tried, and evaluated. For example, a student may dislike a habit of procrastinating, and may decide to try self-rewarding by telephoning a friend or shooting baskets after completing an assignment.

Does the Student Suffer From Disabling Academic Anxiety? Excessive anxiety can result in poorer test performance (Beidel, Turner, & Taylor-Ferreira, 1999). Studies have found that test anxiety affects one-third to one-half of intermediate level students. Anxiety is often identified by individual students during individual interviews, in written self-analysis, or on self-report scales (Reynolds & Richmond, 1985). When students are not sufficiently self-aware to identify anxiety, it can be evident behaviorally such as when they perform significantly better on practice tests than on actual tests.

Achievement anxiety can be addressed directly or indirectly. Direct interventions include relaxation

Grade received			
Comparison of plan and actual studying			
Conclusions			

and/or slow breathing exercises, cognitive behavioral therapy, exercise, meditation, yoga, or even medication. Indirect interventions include instruction in study skills. A comprehensive 11-week program for teaching study skills, modifying behavior, and improving test-taking strategies was found to significantly reduce test anxiety and increase academic performance (Beidel, Turner, & Taylor-Ferreira, 1999). Similarly, in a meta-analysis of research studies on study skill training, Hattie, Biggs, and Purdie (1996) found that instruction in study skills reduces anxiety.

Metacognition

Does the Student Have Metacognitive Skills That Enable Him or Her to Assess His or Her Own Level of Knowledge? Metacognition involves knowledge about and regulation of cognition and results in the ability to evaluate, monitor, and make goals and plans for one's own learning (Brown, 1980; Flavell, 1979; Puntambekar, 1995; Tobias, Everson, & Laitusis, 1999). Good students articulate learning goals, control learning, see it as purposive, reflect on strategies, and monitor the effectiveness of a variety of learning strategies (Puntambekar, 1995).

Several strategies can be employed to increase metacognition. Learning to estimate one's level of knowledge accurately (as assessed by test performance) positively correlates with reading and math achievement, self-monitoring, and strategic help-seeking (Tobias, Everson, & Laitusis, 1999). These skills can also be enhanced by using specifically designed computer programs (Puntambekar, 1995) or through individual or group interventions. As suggested by Sweidel (1996), students can develop "study strategy portfolios" in which they outline and commit to a study plan (noting where, when, and with what strategies they will study) and examine their study strategies (asking: How do you know when you have studied enough? How do you monitor your studying? How do you keep yourself motivated? How many hours do you plan to study? How do you go about reading the material? Did you follow your plan? Did you make modifications? How prepared do you feel? How many hours did you actually study? Do you plan to make changes to your study plan in the future? What grade do you expect to get?). After students receive graded tests and assignments, they compare their study plan and activities with their academic achievement, indicate their satisfaction, and determine which strategies were most and least successful. With each unit the plan is modified, using reflection as a tool to assess and change their own performance (Sweidel, 1996).

Does the Student Consider the Type of Reading Material in Planning How to Approach a Reading Assignment? In approaching a reading task, students should assess the demand of the assignment, select a reading approach accordingly, find effective methods to focus attention on the important ideas, and monitor reading comprehension through self-questioning and review (Scott, Wolking, Stoutimore, & Harris, 1990). The rate of reading should be considerably slower when the student is studying or reading difficult material than when reading comfortable material for pleasure. The student should assess "clicks" (understanding) and "clunks" (non-understanding) at the end of each page, and when non-understanding occurs, take remedial steps such as slowing down, re-reading, looking up material, reading about the same topic in an easier source, asking for help, or making a visual map (Schumm & Radencich, 1992).

Does the Student Plan for Learning? For Example, Are All Materials Necessary for Homework Completion Brought Home? Are Sufficient Supplies Available? "Forgetfulness" can be alleviated by home-school collaboration. At school, the teacher can remind students to check that they have their homework and necessary materials before the dismissal bell. At home, parents can implement a simple behavior management system to reinforce bringing materials home. One effective technique is to require the student to spend time on academic activity even when homework was forgotten. Other parents solve the problem by having the child walk back to school to get forgotten materials or by charging gas money for return trips to a distant school. The following supplies and materials are often necessary: textbooks, index cards, loose leaf notebook paper, folders, spiral notebooks, file cabinet or crate, encyclopedias, dictionary, desk or table, assignment book, calendar, and project supplies.

Does the Student Estimate How Long it Will Take To Complete an Assignment? Is This Time Estimate Used to Make a Daily Schedule? Is the Schedule Followed? Students often have unrealistic ideas of the length of time it takes to complete given tasks. Timing a student completing a worksheet or reading assignment can produce helpful planning guidelines from which goals and check points can be determined. Daily schedules should be written down. If keeping to the schedule becomes problematic, then a behavior management system can be implemented.

Are Short-Term Assignments Kept Track of in a Book Or Log? Are Long-Term Assignments, Tests, Reports, and Projects Kept Track of in a Calendar? assignment books or sheets and calendars should be required of all students who are expected to complete work independently. Increasingly, schools are posting assignments on Internet websites, which can be helpful for those students with Internet access. If a student has considerable difficulty writing down assignments, even with monitoring by the teacher, then a "buddy" can be seated next to the child to make sure assignments are recorded.

Students need specific guidance in learning how to break long-term assignments into small components and integrate the components into their assignment books. The use of a calendar becomes critical for older students who have multiple long-term assignments and multiple teachers.

Does the Parent Regularly Check the Assignment Calendar/Homework Sheet With the Child, as Well as Checking for Notices, Permission Slips, and Other School Communication? Does the Parent Monitor Homework Completion? Children generally need help from their parents in prioritizing activities, establishing consistent homework and bedtime routines, and organizing books, notebooks, and papers for return to school. Even more important, students need their parents to provide structure and praise. Generally, students need less supervision as they get older, and by junior high they often make and keep their own homework schedule. Some adolescents, particularly students with learning disabilities, will continue to need considerable parental involvement.

Does The Teacher Regularly Check the Assignment Calendar/Homework Sheet and Monitor Homework Completion? If home-school collaboration is to be effective, then the strategies must be appropriately monitored by all stakeholders.

Does the Teacher Make Expected Study Strategies Explicit, Discuss Recommended Approaches Regularly in Class, and Convey to Students That He or She Cares About and Desires Their Success? Even at the university level, instructors find that they must express their desire for students to understand the material for students to be successful and motivated learners (Boelkins & Pfaff, 1998).

Is There a Regular, Quiet Time to Study at Home? Helping parents and students agree upon a study hour is one of the simplest, yet most effective, interventions. Finding a quiet time to study can be very challenging in busy households, and the establishment of a daily study hour must take into account already scheduled extracurricular activities, chores, favorite TV shows, computer games, and the recreational use of the Internet. In addition to these factors, the student's ability to concentrate at different times of the day should be considered. Some can focus much better in the early morning, others after supper, and others right after school. Many elementary school children are too tired after dinner to be able to concentrate efficiently, demonstrated by their being easily frustrated and slow to complete tasks. Ideally, the family agrees upon a study hour, the television and other distractions are turned off, phone calls are not taken, and the entire family studies, reads, or completes paperwork.

Is There Adequate Communication Between the Home and School to Support Homework Completion? School personnel expect that students will study at home. The expectation for independent reading and studying increases in the higher grades. Home-school collaboration is imperative. Teachers need to communicate with parents about problems with homework, and parents need to be available to help with homework and organization. Parents should let teachers know when excessive time is being spent on homework, particularly by disabled students, so assignments can be modified.

Is There Adequate Support at Home to Foster Good Study Strategies? When studying at home is not possible or parents are unable to help the child study appropriately, the school psychologist can help the student develop alternative locations and supports. For example, many schools and community organizations such as Boys and Girls Clubs have after-school programs for elementary school students that include supervised study periods. Most high schools have after-school help provided by teachers, although students may need help accessing transportation. These can supplement supportive study halls during the school day.

What Does the Student Do When Unable to Understand Something at Home? Some parents are clearly more skilled at helping with homework than others, and some students have no one whom they feel comfortable asking for help. If this is the case, students will need help brainstorming how they might solve this dilemma. Sometimes a neighbor or another family member (older sibling, cousin, or grandparent) can be helpful; some communities have a homework hotline; and some students prefer to ask a teacher for help before school, after school, or via e-mail. Often it is helpful for students to have "study buddies," peers who share telephone numbers and call one another for help or to talk through assignments. In advanced math and science, collaborative learning with study buddies and study groups can be extremely helpful methods for increasing comprehension (Derek Bok Center for Teaching and Learning, 1993; Treisman, 1992).

Can the Student Assess His or Her Own Preferred Learning Style to Determine the Best Environment for Studying and Then Work With His or Her Family to Obtain This Environment? Where Does the Student Prefer to do Homework? Is There a Place at Home to Study That is Quiet and Well Lit, With a Table or Desk? Where a student prefers to study needs to be taken into account. For many students, the ideal location is an environment devoid of distractions. Some students find working in their own room difficult because they are tempted by distractions or they are lonely and seek attention to alleviate loneliness. Such students may study better at the kitchen table or another location. Other students may prefer to work at the library, and transportation will need to be negotiated. The most effective strategy is for a student to study in one place, so efficient studying is associated with that location.

Cognitive Strategies

ORGANIZATION

Are Assignments Turned In With a Label, Name, and Date? Are They Neat? Are They complete? Are assignments Checked For Errors and Corrected Before Being Turned In? Students need to develop the habit of automatically checking their work before turning it in. One method is for the teacher to give the entire class time to check over their work before collecting it, and fade active monitoring across time. On the individual level, papers can be turned back to the student (non-punitively) when it is apparent that checking is needed. The acronym COPS can be used to remind to check for Capitalization, Overall appearance, Punctuation, and Spelling (Wiens, 1983).

Does the Student (Grade Four and Below) Keep One Folder for Assignment Sheets, With "Work To Do" On the Left and "Work To Turn In" On the Right? This is an extremely effective method for managing worksheets in the lower grades. Often children at this age level find "Trapper-keepers" and notebooks too cumbersome and confusing.

Does the Student (Grade Five and Above) Keep a Loose-Leaf Notebook or Notebooks Organized Chronologically, By Subject? Organizational skills have been found to be significantly correlated with both standardized test results and academic achievement (Foley & Epstein, 1992). Loose-leaf notebooks are most efficient because handouts and notes from the textbook can be added in chronological order. Each subject should be separate. There should also be a pouch for supplies and a section for assignments. To be effective, notebooks must be maintained in an organized manner, which requires monitoring by teachers for several years.

Does the Student Come to Class With Notebook, Pencil, Completed Homework, and Textbook? Students need a certain place at home to keep materials "to go to school." It is important that this place not be cluttered with other materials.

Is the Student's Desk, Cubby, or Locker Neat Enough to Locate Required Materials Quickly? Teachers can designate times for the entire class to clean out both desks and notebooks. Students with severe organizational problems will need an adult or organized friend to help sort their papers. Unscheduled and scheduled checks, with rewards for good organization, are helpful. For students who become disorganized between classroom cleanups (for some students this can be daily), a cleaning routine should be established, with neatness criteria, timeline, and reinforcements so major cleanups are not necessary.

LISTENING SKILLS

Are Directions Understood? The comprehension of oral communications is often assumed, yet students frequently do not understand what is said to them. Comprehension of directions can be checked by having students tell you, in their own words, what needs to be done. It is helpful for younger students to write (circle, if the directions are written) each action word, number each action, and cross off each number after completion (Kuepper, 1990).

Are Directions Followed? If students understand the directions, yet still do not follow them, then perhaps they do not attend to directions or they do not want to follow directions. The former can be remedied by having the student read the directions sub-vocally before starting the paper. Lack of desire to follow directions needs to be further explored in an expanded student interview to determine the function of the behavior and benefits (such as adult attention) the student gains from noncompliance and to delineate alternate methods to obtain the same benefit.

Does the Student Listen In Class? Not listening in class can be caused by many factors, including chronic or intermittent hearing loss, preoccupation with personal issues, a boring presentation, weak listening skills, or deficiencies in auditory processing. Listening skills can be assessed by using standardized instruments including the Woodcock-Johnson Psychoeducational Battery-Revised (McGrew, Werder, & Woodcock, 1991) or the Clinical Evaluation of Language Fundamentals-Revised (Semel, Wiig, & Secord, 1989). The latter assesses comprehension of oral directives, sentence structure, linguistic concepts, and oral paragraphs.

NOTE-TAKING SKILLS

Are Notes Taken In Class? Note taking has several advantages, including the improvement of material acquisition. Students who take and review notes score higher on tests than students who do not (Baker & Lombardi, 1985). Further, the more often notes are reviewed, the better the achievement. Having students mark a "review tally" each time they review their notes encourages spaced reviews (Lazarus, 1996).

Does Each Page of Notes Have the Date and Topic Written At the Top? Notes should be orderly, labeled, and legible, written in the student's own words, and contain all key words and some supporting details.

When listening to lectures, students tend to miss 50% or more of the main ideas (Baker, & Lombardi, 1985). Therefore, teachers should assess students' abilities to take orderly notes, and provide supervised practice as appropriate.

A very effective method to teach note-taking skills is to provide "flexible skeletons," or outlines of lectures with missing material. As the lecture proceeds, students fill in the missing portions of the outline. At the end of the period, the teacher can check randomly chosen outlines for accuracy.

Are Details Added to Class Notes As Soon As Possible After Class? Completing notes right after class is extremely beneficial because it provides another learning trial and students are better able to remember and correct details if only a short time has elapsed.

Is a Note-Taking System Used? Learning-disabled students are often encouraged to use laptop computers for in-class note taking. The use of an outlining function in a word processing program can be an effective tool for this purpose, and some computer programs have the additional capacity to move from an outline function to a graphic organizer function (Anderson-Inman, Knox-Quinn, & Horney, 1996; Tenny, 1992). Computers can act as an intermediary between print and understanding by enabling the student to manipulate information, structure hierarchically, insert additional information and delete unessential information, and reorganize the information. Computers also facilitate moving from one source (file or program) to another and enable the student to view information from multiple perspectives (Tenny, 1992).

The Cornell Method (Pauk, 1974) is elaborate and time consuming, but effective. The student *Records* notes during lectures, *Reduces* those notes within 24 hours to as few key words as possible, *Recites* by looking at the keywords and attempting to recall the lecture, *Reflects* about the main ideas and any poorly understood concepts to ask about, and *Reviews* notes periodically. This method effectively combines note taking with systematically spacing the learning and checking for comprehension.

Are Relevant Reading Materials Pre-Read Before the Lecture On the Same Material? Pre-reading greatly increases understanding of a lecture. It also is another method to space learning trials and produces much better retention. It has the added advantage of encouraging the student to focus on unfamiliar words or concepts and ask about them in class.

READING SKILLS

Does the Student Pre-Read? Pre-reading takes very little time but is one of the most important techniques to aid in understanding material. Nonfiction is pre-read by reviewing non-text cues (title, author, publication date, headings and subheadings, picture, graphs, charts), reading the introduction, preface, and conclusion, and skimming the body. Fiction is pre-read by reading the front cover, back cover, and introduction, and skimming the first 25% to determine setting, character, and plot.

When There Are Words That the Student Does Not Understand in the Reading Does the Student Determine Their Meaning and Write Them Down? SSCD (Devine, 1987) provides four approaches to unfamiliar words: *Sound* (students sound out the word to see if it is already in their listening vocabulary), *Structure* (analyze the word for familiar prefixes, suffixes, and roots), *Context* (guess at the meaning using clues in the surrounding passages), and *Dictionary* (use the dictionary or glossary to look up unfamiliar words).

Is the Student Easily Distracted Or Bored While Reading? If a student is easily bored or distracted, then it can be helpful to determine how long the student can concentrate and have him or her take a brief break every so often. Taking notes, outlining, mapping, and writing down questions while reading also aid attention. Other techniques include relating something already known to the topic being read, predicting what will come next, visualizing the material (making a mental movie), and making timelines or flowcharts to track events while reading.

Are Personal Copies of Textbooks Available to the Student? Does the Student Know How to Take Notes in Textbooks by Highlighting or Making Margin Notations? Personal copies of textbooks enable students to use them more effectively. Writing margin notes in reaction to the text is more effective than highlighting because it is more active. When highlighting or underlining is used, only one or two topic sentences per paragraph should be highlighted.

Is a Reading Technique Used When Reading Difficult Assignments? There are four techniques to increase the reading comprehension of difficult materials: paraphrasing, self-questioning, visual imaging, and summarizing (Gajria & Salvia, 1992). One of the best known strategies, SQ3R (Robinson, 1961), involves the following steps:

1. Survey: Look over the material before beginning to read to obtain a general framework in which to store supporting details. Pay particular attention to the title, chapter headings and subheadings, charts and pictures, the introductory paragraphs, and the conclusion.

2. Question: Write down questions about the material before beginning to read. These questions should reflect curiosity about the topic. Another source of questions is to convert headings and subheadings into questions.

3. Read: Read through the material in the normal way. Add unknown words to a list.

4. Recite and write: Give the answers to the questions to another person or write them down. Summarize the material in writing.

5. Review: Go over the material several times before being tested, attending particularly to the author's purpose and key points, until the information is well known.

Does the Student Outline or Take Notes From Reading Assignments? Taking notes from reading or computer-generated material has been repeatedly shown to significantly increase learning, both because of the process of note taking itself and because it generates a product useful in reviewing for exams (Armel & Shrock, 1996). Outlining is one of the most effective recording techniques because it succinctly summarizes a large volume of material into a hierarchical presentation, with clear demarcation of the most important issues in headings. Outlining is frequently taught in the intermediate grades, but students' ability to outline should also be checked at the secondary level and taught and reinforced across curriculum lines. Students who are overwhelmed sometimes find the use of index cards for summary and review an effective method to handle volumes of material.

Does the Student Know How to "Map" A Reading? One method that promotes visual imaging is "mapping" readings. In so doing, the main topic is placed in the middle of a blank sheet of paper. Subheadings branch from the main topic, and supporting details branch from the subheadings. This creates a highly effective visual aid that increases organization and comprehension (Sebranek, Meyer, & Kemper, 1998).

Does the Student Know How to Summarize Effectively? Another strategy, summarizing written material, has been found to significantly increase the comprehension of written material (Gajria & Salvia, 1992). Effective summarizing requires selecting or inventing a topic sentence for each paragraph, determining which material is unnecessary and deleting it, and substituting superordinate terms for lists. Computers can be used to assist with these strategies. Most word processing programs have an outline function that can be used to facilitate outlining texts, serving as powerful tools to improve comprehension of textbook materials (Anderson-Inman, Knox-Quinn, & Horney, 1996). Further, some computer-based mapping programs are able to convert outlines into graphics and vice versa, enabling students to synthesize scientific concepts and information. Learning-disabled students provided with laptop computers can minimize the negative aspects of their learning disability and enhance their sense of self-efficacy and responsibility of academic success. Anderson-Inman, Knox-Quinn, and Horney (1996) indicate that this requires specifically teaching the students a three step process:

1. Create a chapter skeleton by typing headings and subheadings into an outlining program

2. Carefully read each paragraph and insert key words and main ideas into the outline

3. Test their knowledge by expanding and contracting the outline to show or hide material and then asking "how many?" "what are they?" or "what more do I know?" (p. 470).

Does the Student Use Headings and Other Typographical Aids? Can the Student Read Tables,

Charts, and Graphs? Does The Student Know How to Use the Table Of Contents and Index of a Book? These skills are surprisingly often not present: in one study, only 2 of 133 sixth-grade students who were experiencing school difficulty were able to use an index, a biographical dictionary, read graphs, read maps and map keys, use headings, and outline a chapter (Leland-Jones, 1997). These abilities can be checked by having the student show the school psychologist the textbook, read some of the graphs and charts, and find items using the table of contents and index.

Is the Student Able to Comprehend Textbooks? Several methods may determine a student's ability to comprehend the assigned textbook. First, it is very useful to have the student review the textbook orally, explaining the pictures, graphs, and general material in a previously studied chapter. Second, have the student read aloud a passage from the text. In instructional material, the student should be able to read with 90% word-calling accuracy and 75% accuracy in answering comprehension questions. If more challenging material, on which the child makes more than 15% word-calling errors, is assigned, additional instructional support is needed (Scott, Wolking, Stoutimore, & Harris, 1990).

A second method to assess a student's ability to comprehend content material is to devise a cloze test. This is done by photocopying approximately 260 running words from the text. The first sentence is left complete, and then one of the first five words in the second sentence is blanked out, as is every fifth word until there are fifty blanks. Finish with a complete sentence. The student then reads the passage, guessing the missing words. The student should be able to guess at least 60% of the missing words (Jacobson, 1990).

A third method is to determine the readability level of the textbook and compare this score with the score obtained on a standardized reading test. Publishers often calculate readability through one of the several indices, and readability levels can also be calculated by typing a passage into a word processing program and having the computer calculate the readability with the grammar checker.

Several strategies can be used when a student is found to be unable to comprehend a text: audio taping the textbook, using high-interest low-vocabulary materials, teaching textbook structure, pre-teaching, providing advance organizers (which might include the teacher's notes), and teaching textbook reading strategies (Meese, 1992; Devine, 1987). A number of computer programs have been developed that specifically increase reading comprehension, improve reading vocabulary, and increase reading speed. Many of these can be tailored to particular curriculum areas, for example, social studies vocabulary can be inserted (Vockell, 1992).

Computer-assisted instruction materials have been developed by a number of textbook authors, and these can be extremely useful to increase comprehension. Computer-assisted instruction uses a computer program, often on a CD-ROM or in "interactive video disc instruction," to guide and individualize instruction. These strategies have been found to greatly increase knowledge of social studies (Higgins & Boone, 1990), algebra (Kime & Clark, 1998), word recognition and decoding (Wise & Olson, 1994), and biology (Jones, 1993).

Can the Student Predict Outcomes, Distinguish Fact From Opinion, Discern Emotional Appeals, Recognize Bias, and Discern Inference? If not, then the student will find it difficult to understand reading material at the secondary level. These critical thinking skills typically are taught in the intermediate grades, but most students will require additional instruction throughout their schooling.

MATH AND SCIENCE SKILLS

Strategies necessary for the acquisition of math and science skills and knowledge are somewhat different from the strategies necessary for courses requiring substantial reading and writing such as English and History. However, these study strategies are so rarely taught that 50% of college-level math and engineering majors fail exams and courses, and an even greater number of students avoid math and science courses altogether. Fortunately, math and science study skills are quite teachable and, when incorporated into the curriculum, can improve the exam-passing rate significantly (Boelkins & Pfaff, 1998). Similar results have been found with students at the community college level, where study skills instruction resulted in approximately 20% more of the students passing math courses (Seon & King, 1997).

Does the Student Work on Math and Science Problems on a Daily Basis? Math and science skills are substantially improved by spaced learning. Studying and completing math and science problems daily is vastly superior to cramming before tests. Studying one hour daily results in significantly higher grades than studying eight hours the day before a test.

Does the Student Employ an Outline or Use 3 X 5 Flash Cards to Help Learn and Remember Definitions, Important Ideas, Key Examples, and Theorems? When teachers require these as specific assignments, they are much more likely to be completed. These should be developed well in advance of tests, several times per week, and reviewed several times. Students can develop their own flash cards, although they should be edited for accuracy. Students can also be encouraged to understand that moving from calculation to rote recall to instantaneous recall is desirable, not in an end of itself, but to facilitate problem solving in the future.

Does the Student Know How to Use a Scientific Calculator? A Graphing Calculator? Calculators are an essential component in many high school math classes and are now an integral element in the calculation of complex problems currently presented.

Does the Student Estimate the Answer in Conjunction With Using a Calculator? If students use calculators blindly, without making estimates, then they easily miss correcting minor errors that result in nonsensical answers.

Does the Student Review Problems Already Completed? Does the Student Try New Problems That Were Not Assigned? Students make much more effective progress when encouraged to be cognizant of their skill levels and to differentiate routine, review, and challenging problems (akin to reading at the independent, instructional, and frustration level). Teachers can encourage this practice by daily assigning routine problems from the current lesson, harder problems from recent lessons, and some review problems. Such assignments give the students explicit guidance in working with easier problems first, obtaining corrective feedback, and asking questions before progressing to harder problems (Boelkins & Pfaff, 1998).

Does the Student Choose Problems From a Variety of Sections to Test Understanding? Working on only one type of problem at a time can result in the rote application of procedures. In contrast, working on a mixture of problems enables students to move toward learning to apply ideas in varied contexts. It also promotes retention and helps prepare for tests.

Does the Student Participate In a Study Group? Often working toward comprehension in math and science requires students to work collaboratively, discussing and correcting each other's understanding of concepts and procedures (Derek Bok Center for Teaching and Learning, 1993). Such collaborative learning can take place in the classroom or after school in study groups. Study groups who work together, on a nightly basis, until every member of the group not only completes the homework correctly but also *understands* the concepts and process, raise grades for all participants (Treisman, 1992).

REPORTING SKILLS

Does the Student Know How to Find Information Using Books, Maps, Graphics, Newspapers, Dictionaries, Libraries, the Internet, and Other Reference Tools? A substantial number of computer programs have been developed to facilitate information retrieval. For example, there are tools that encourage the use of libraries (both hard copy and electronic) to develop research skills. Many of these are simply electronic versions of hard copy predecessors. However, the Internet is clearly a unique tool, and students need instruction in determining the appropriateness of Internet-garnered information.

Can the Student Use the Computer Catalogue in the Library and Then Locate the Material? Can the Student Use the Periodical Index? Surprisingly large numbers of older students are not independent in using these essential resources, and even college students often require additional instruction in library research techniques.

Does the Student Organize Papers, by Outlining or Using a Story Map, Before Writing? Does the Student Write a First Draft? Does the Student Proofread for Success/Failure in Answering the Purpose of the Assignment, Legibility, Neatness, Spelling, Complete Sentences, and Punctuation Errors? Again, these skills typically are taught in the intermediate grades, but most students will require additional instruction throughout their schooling.

With Which Reporting Techniques is a Student Familiar? Most Capable? Which Does He or She Prefer? Besides the traditional oral and written reports, nonverbal reporting techniques are available. These include preparing charts and graphs, making models, drawing maps, dramatic presentation, and using pictures or photographs. The use of these techniques is not limited to the traditional subject; for example, maps can be employed in English class to indicate dialect use (Devine, 1987). Many students, particularly those with learning disabilities, prefer to use nonverbal reporting techniques, and the school psychologist can consult with the classroom teacher to help develop appropriate nonverbal reporting techniques in various content areas.

Is the Student Skilled In Using Word Processing for Assignment Completion? The use of word processing greatly facilitates legibility and efficiency. However, students must be specifically taught keyboarding and effective word processing skills (including editing, cutting and pasting, other revision mechanism, spelling and grammar checkers, and electronic dictionaries and encyclopedias). Many of these skills require specific strategies. For example, students must be taught how to determine which of the alternative suggestions generated by a spelling checker are correct (Anderson-Inman, Knox-Quinn, & Horney, 1996). Writing papers requires the ability to locate and synthesize information. Using computer outlines and word processing programs greatly facilitates this process, particularly for learning-disabled students (Anderson-Inman, Knox-Quinn, & Horney, 1996).

TEST-TAKING HABITS

Does the Student Space Learning Over Several Sessions (Versus Cramming) and Use a Study Plan? Does the Student Conduct Weekly Reviews? Studying for a test should be spread over several days and divided into several small units. Research has demonstrated that spaced practice results in more efficient learning than massed practice.

Does the Student Predict Test Questions? Having a student develop multiple choice, short answer, and essay questions while studying is a very effective study technique. In addition, many students find answering predicted test questions aloud to be particularly effective.

Does the Student Know and Use Good Test-Taking Strategies? These include coming to the exam with everything needed; reviewing the directions carefully, including any sample items; skimming through the entire test to determine its scope; setting up and keeping a schedule; reading each question carefully (on essays, responding precisely to words such as discuss, describe, illustrate, explain, evaluate; on multiple choice, being wary of words such as always, never, everyone); outlining the important points to be covered before responding to an essay question; postponing an extremely difficult question; attempting to answer every question; writing neatly; and rechecking work before handing it in (Deese & Deese, 1979).

Does The Student Study Using the SQ3R (see Reading Study Skills) or a Similar Method? Does the Student Use Study Guides While Studying? In addition to using study guides provided by teachers and in the textbook, it is helpful for the student to group information into meaningful units. "Mapping" and other visual aids are particularly helpful to this end. Study guides can be in the format of outlines or graphic organizers, but are most effective when incomplete so students can add their own elaborating and experiential information. Such active interaction with study guides results in improved performance. This practice can be facilitated by the teacher's providing incomplete notes, having students complete them, and then checking them for accuracy (Katayama, 1997).

SUMMARY

Study skills significantly affect students' school functioning and can be taught at all ages and levels of ability. Teachers often do not provide instruction in study skills because they assume that students already have mastered them. Frequently, interventions to improve organization or study skills can be implemented in prevention programs or pre-referral stages, preventing the need for more extensive assessments and interventions. School psychologists' training in human learning and memory, assessment of individual differences, the application of curriculum-based assessment, consultation, the scope and sequence of instruction, behavior management plan implementation, anxiety reduction strategies, counseling, and the provision of in-service training to teachers greatly facilitates their work in improving students' study skills. Furthermore, school psychologists can effectively influence both teachers and curriculum so that study skills are addressed across curriculum lines.

The most productive assessment method uses an ecological approach, involving classroom observations, analyses of work samples, consultations with teachers and parents, student interviews, observation of the student at work, and having him or her describe work method and study techniques. One must precisely identify areas of weakness to design effective remediation. This chapter considers the assessment and treatment of affective, metacognitive, and cognitive aspects of study skills deficiencies. Questions to supplement clinical interviews are provided, as well as a checklist of classroom characteristics facilitating good study skills. Effective remediation requires that the school psychologist, student, teacher, and parent work together closely to determine appropriate procedures, designate responsibilities, and design techniques to encourage generalization.

Best Practices in Reading, Writing, and Math Assessment-Intervention Links: A Systems Approach for Schools, Classrooms, and Individuals

Virginia Wise Berninger
University of Washington

OVERVIEW

To prepare all students to have sufficient literacy and numeracy skills for an increasingly technological society, school psychologists should focus on big problems in academic skill development and not just the little problems one student at a time (Shapiro, 2000). That is, school psychologists should facilitate organizational change, with the goal of preventing reading, writing, and math disabilities and optimizing the academic achievement of all students throughout schooling. This approach does not imply that the school psychologist has to accomplish this organizational change alone. Rather, this approach envisions that the school psychologist, as a member of a multidisciplinary team of educational professionals, works with colleagues toward achieving the goal of systems level change. However, this approach does encourage the school psychologist to be a catalyst in mobilizing the team to institute a plan for achieving organizational change that would optimize the educational achievement of all students.

A three-tier model for implementing such organizational change has been described for reading and writing (Berninger, Stage, Smith, & Hildebrand, 2001) and math (Busse, Berninger, Smith, & Hildebrand, 2001). Each of the tiers is supported by empirically based evidence from a systematic line of programmatic research over the past two decades conducted by school psychologists at the University of Washington. This line of research, funded by the National Institute of Child Health and Human Development (NICHD), is unique in that it focused on (a) linking assessment and intervention and (b) integrating code and whole language approaches in reading, and integrating basics skills and process writing approaches in writing. A second line of research, funded by the U.S. Department of Education, focused on both math talent and math disability. In the first tier, school psychologists implement school-wide screening based on empirically validated measures to identify students at-risk for reading, writing, or math problems and then design early intervention programs based on empirically validated research on how children learn reading, writing, and math. School psychologists then consult with general educators or supervise paraprofessionals or community volunteers who implement these intervention programs (cf., Vadasy, Jenkins, Antil, Wayne, & O'Connor, 1997) and then monitor student progress by using norm-referenced, criterion-referenced, and curriculum-based measures and portfolios. In the second tier, school psychologists use problem-solving collaboration for designing and evaluating pre-referral intervention for any student at any grade level who is referred to the multidisciplinary child study team. This tier has been widely discussed in the school psychology literature. In the third tier, school psychologists perform individual diagnostic assessments for those students who do not respond or respond very slowly to early or pre-referral interventions for the purposes of (a) differential diagnosis and (b) individual educational planning tailored to all the necessary components of functional reading, writing, and math systems.

Schools that have used such alternative assessment-intervention models aimed at prevention through organizational change have found that (a) the number of special educational evaluations is substantially reduced and (b) school psychologists have more time for providing psychological services other than testing (e.g., see the work of Stage and collaborators in Berninger, Stage et al. (2001) for illustration with the Washington State Student Responsive Delivery System). All three tiers require consultation skills that include both process and content expertise. Process expertise in problem-solving skills is necessary but not sufficient. Content expertise in scientific knowledge of the literacy and numeracy acquisition processes and research-supported instructional practices is also necessary. This chapter will provide resources for school psychologists who wish to acquire such content expertise in the academic domain.

Furthermore, school psychologists can contribute to organizational change in additional ways beyond how assessment-intervention services are delivered in the local school. They can also consult at the district and local school level about the latest research on empirically supported assessment and intervention practices and about appropriate ways to evaluate educational achievement. This kind of consultation includes workshops to disseminate knowledge about empirically supported assessment and intervention practices. Of all the professionals in a school, the psychologist is likely to have graduate level training in how to read research literature in the academic domain and in how to apply educational measurement and statistics to academic assessment and intervention. Considerable research on reading, writing, and math over the past two decades has advanced our understanding of how children normally acquire literacy and numeracy skills and why some children struggle to do so. For example, the U.S. Congress convened a blue ribbon panel to review the sizable body of research on reading instruction, and their conclusions are now available to school practitioners (National Institute of Child Health and Human Development, 2000). Considering the bipartisan support for the national mandate that all children should be readers by the end of third grade, school psychologists have an important role to play in disseminating this research information to their colleagues through the consultation process, which includes continuing education of colleagues.

At the same time, as part of a national educational reform movement, most states have adopted standards to raise academic achievement and developed assessment instruments to evaluate whether students are meeting these standards. Although academic excellence is a laudable goal, this standards-based, high-stakes assessment is still a work-in-progress, with many measurement issues that have not been fully resolved in all states (e.g., developmental appropriateness of some of the tasks, inter-rater reliability and test-retest reliability, and validity for performance outside the classroom). These issues may receive increased public and legal scrutiny because some states tie performance on these tests with high school graduation and teacher pay and grapple with whether to hold students with diagnosed learning disabilities to the same standards as students without disabilities. Further, state officials, politicians, and the public do not always understand the statistics underlying educational assessment. For example, a public official noted that there are as many students below the 50th percentile today as there were 10 years ago, prompting the author to realize what a valuable role the school psychologist might play in educating the public, parents, and other educational professionals about the measurement issues for a variety of modes of educational assessment (e.g., norm-referenced, criterion-referenced, curriculum-based, and portfolio-based).

To begin with, school psychologists might propose more realistic alternatives to the Lake Wobegon mentality in which every student is expected to be above average, a statistical impossibility. One alternative might be to include more emphasis on acknowledgment of human diversity in abilities and on educational planning and programming that takes this diversity into account and does not hold all students to a single standard. Another alternative might be to develop algorithms for basing educational decisions such as student graduation and teacher effectiveness on multiple sources of information: state mandated assessments, school system testing programs, individual assessments (conducted by school psychologists, speech and language specialists, or special educators), and assessments by classroom teachers (e.g., portfolios). Another alternative is to place more emphasis on evaluating on an annual basis whether *every* student is achieving more at the end of the school year than at the beginning of the year on each specific curriculum goal. In the proposed systems-based assessment-intervention approach, educators should not lose sight of normal variation among students in starting and ending points each school year and the alternative paths students follow in achieving their learning outcomes (Berninger, 1998a).

Combining the previously described three tiers of assessment-intervention with consultation at the school system and building levels on research-supported knowledge of academic functioning and measurement issues will probably have more impact than merely problem solving with one teacher at a time about a single student (cf. Shapiro, 2000). The school psychologist could have positive impact on school systems, local schools, classrooms, and individual students, but will need training to achieve this goal of organizational change in academic assessment-intervention. For example, to prepare pre-service school psychologists for this expanded role of organizational change, students in the school psychology program at the University of Washington are asked to design their own screening and early intervention program (tier 1), procedures for curriculum modification and progress monitoring within a problem-solving consultation framework (tier 2), and individual educational plans aimed at all necessary components of functional reading, writing, and math systems (tier 3). They are also asked to design workshops to update educators on recent research on academic assessment and instruction. They are also asked to apply their knowledge of educational measurement and assessment to hypothetical cases involving state standards for reading, writing, and math. They are also expected to acquire hands-on experience in academic intervention through practica (and in many cases intervention research studies) in order to be better prepared for their roles as consultants with teachers or supervisors of paraprofessionals in implementing academic interventions. Because most practicing school psychologists need continuing education for this new role, this chapter is designed to call school psychologists' attention to resources for achieving this immense goal of organizational change based on empirically supported assessment and intervention practices.

To accomplish this aim, the chapter provides four kinds of information relevant to best practices: (a) resources for readily accessing the relevant research knowledge; (b) resources for research-identified reading, writing, and math skills that should be assessed and addressed in early intervention plans, pre-referral intervention plans, and individualized educational plans; (c) resources for alternative assessment instruments and alternative instructional programs and curriculum materials for these academic skills; and (d) empirically supported general principles for assessment and intervention practices for reading, writing, and math. Given space limitations, complete information on how to implement the recommended practices cannot be provided in this chapter. However, taken together, four resources (Berninger, 1998a, 2001; Berninger, Stage et al., 2001; and Busse et al., 2001) do provide this information, especially the first resource, which is a textbook designed to integrate theory, research findings, and practice.

BASIC CONSIDERATIONS IN OBTAINING RESOURCES FOR THE RELEVANT RESEARCH KNOWLEDGE LANGUAGE

Proficient assessment and intervention plans for reading and writing require that professionals have a thorough understanding of language development. Moats (2000) offered a systematic introduction to phonetics, phonology, morphology, semantics, and syntax of English. School psychologists can use this text (which explains complex linguistic concepts clearly in an easily understandable format) for workshops that are aimed at preventing literacy problems. The information is also directly applicable to interpretation of errors students make during assessment and to generation of instructional recommendations. The exercises at the end of each chapter, which provide concrete examples for translating the linguistic concepts into educational practice, are ideally suited for use in workshops. Either the brief or the comprehensive survey of language can be given before and after a single workshop or series of workshops to assess knowledge change of participants. Both the school psychologist and the speech and language specialist might conduct such workshops. The American Association of Speech, Language, and Hearing (ASHA) recognizes that speech and language specialists need more training in language and its application to learning academic skills and has set that as a professional goal (Joint ASHA-NIH Conference, September 21–23, 2000) School psychologists who desire additional training in research-generated knowledge of aural/oral language, reading, writing, and math acquisition might take university courses for their continuing education requirements or their individualized professional development plans that some states now require.

Reading

Adams (1990) offered a comprehensive introduction to the research on beginning reading instruction, and the conclusions of this synthesis of the research literature are consistent with the conclusions of the National Reading Panel a decade later (National Institute of Child Health and Human Development, 2000). Blachman (1997) reported more recent research findings regarding assessment and instructional practices in reading that are relevant to all the assessment-intervention tiers in this chapter. Likewise, the chapters on reading in Wong (1998) provided an overview of current research on reading that is relevant to all three tiers and spans literacy in early childhood to middle childhood to adolescence. Clark and Uhry (1995) focused specifically on research on diagnosis and treatment of dyslexia, which is a reading disorder that affects word recognition and decoding. Birsh (1999) described a variety of multi-sensory and structured language methods for teaching reading and other academic skills to students with learning disabilities.

Balmuth (1992), Henry (1999), and Moats (2000, Chapter 5) are valuable resources for any professional who assesses or teaches written language skills, and these references provide a deep understanding of how English phonology is represented in English orthography. These representations depend to a large degree on whether words are immigrants to the language from the Anglo-Saxon layer, the Romance (French and Latin) layer, or the Greek layer. This information is relevant in assessing and generating instructional recommendations for the phonological decoding process, which varies somewhat across these layers of word origin. For example, the /sh/ phoneme is represented by sh in the Anglo-Saxon layer (e.g., shine) but by ti or si or ci in the Romance layer (e.g., nation, passion, ancient); the ch spelling represents the /ch/ phoneme in the Anglo Saxon layer (e.g., child) but the /k/ phoneme in Greek layer (e.g., psychology). Most words in primary grade reading material are from the Anglo-Saxon layer, whereas many words in intermediate grade reading material are from the Romance layer and many words in science and technical texts are from the Greek layer. Thus, instructional recommendations for helping students at any grade level to transition from beginning reading skills to intermediate reading skills should include instructional materials with sufficient words from the Romance and Greek layers and explicit instruction in the morphology (meaning and grammatical information signaled by word structure) related to word origin (Henry, 1990, 1999).

The *Process Assessment of the Learner (PAL) Guides for Reading and Writing Intervention* (Berninger, 1998a), which will be referred to as the *PAL Intervention Guides*, described a conceptual framework for integrating research on reading (and writing) assessment and intervention. In an approach that differs from the individual educational plans (IEPs) used in schools, this resource provides forms, which can be duplicated, to plan comprehensively for *each necessary instructional component in reading (and writing)* and for *integrating these instructional components* for individual students within and across general and special education classrooms and throughout the instructional day and week. This approach is also unique in that it allows for teacher judgment as to how each of the necessary components might be taught and lists commercially available resources from which teachers can choose for each of these necessary instructional components. Implementation of this integrated assessment-intervention approach also draws on the practical suggestions Shapiro (1996) made for multimodal assessment of reading for purposes of educational planning and progress monitoring.

Writing

Graham, Harris, MacArthur, and Schwartz (1998) compared skilled writing and the writing of students with learning disabilities, described the process approach to writing instruction that is widely used, explained the role of strategy instruction in developing self-regulated writing, and discussed research on effective ways to teach handwriting, spelling, and composition. Moats (1995) integrated what is known about normal developmental processes of spelling and spelling disability. Harris and Graham (1996) summarized effective ways of teaching students strategies for self-regulation of the writing process. The *PAL Intervention Guides* (Berninger, 1998a) reviewed assessment and intervention research for handwriting, spelling, and composition and listed commercially available resources for each of the component writing processes and related language processes. Taken together, these resources provide entry to the literature on writing disabilities, which are under-diagnosed and under-served when compared with reading disabilities.

Math

Resnick and Ford (1981) described the cognitive processes for learning and teaching math from a developmental perspective, which is important for understanding math curriculum. Geary (1993) proposed neuropsychological subtypes of math disabilities, including difficulties with semantic retrieval of math facts, application of computational algorithms, and visual-spatial understanding of the number system, which is important for differential diagnosis. Fleishner and Manheimer (1997) discussed myths and realities for teaching students with math disabilities and offered practical instructional recommendations. Busse et al. (2001) synthesized a growing research literature that shows that math disabilities may be specific to problems in automaticity or strategy use or both and introduced a conceptual model of the domain-specific and domain-general components of the functional math system. This model can be applied to both interpreting assessment results based on a variety of instruments and generating instructional interventions for the math domain for both math talent and math disabilities.

General Principles Across Reading, Writing, and Math Domains

Memory processes play important roles in learning to read, to write, and to do math. Short-term memory (STM), long-term memory (LTM), and working memory (WM) contribute differentially. Whereas STM encodes incoming information from the environment in temporary stores and LTM stores information on a more permanent basis, WM (Swanson, 1995a, 1995b) stores information from STM and LTM while processing for specific reading, writing, or math goals takes place (see Swanson, Cooney, & O'Shaughnessy, 1998). Working memory is therefore an important mechanism for integrating low-level and high-level goals in academic learning (see general principle discussed later in this section). Swanson's Mental Processing Battery (Swanson, 1995a) has measures of working memory that have been validated in the University of Washington research program for assessing reading and writing skills. Classroom and clinical performance on reading, writing, and math activities or tests should be task analyzed as to whether bottlenecks may be occurring in STM, LTM, and/or WM within or across academic domains and, if so, to generate instructional recommendations to deal with specific bottlenecks.

Executive functions for managing attention and self-regulating goal-directed behaviors also play an important role in learning all academic skills. For example, Swanson (1999) reported evidence for an executive dysfunction disability subtype in addition to the phonological core subtype of reading disability. Lyon and Krasnegor (1996) provided a comprehensive resource for research on memory and executive functions related to learning academic skills. Executive functions should be assessed because learning is as dependent on child-directed, self-regulated learning as it is on teacher-directed, other-regulated instruction. Students who have difficulty with executive functions need explicit instruction in self-regulation strategies for guiding their independent learning (e.g., Harris & Graham, 1996).

Another general principle is that assessment and intervention should address both automaticity of low-level skills *and* strategies for higher-order thinking and problem solving. Automaticity of word recognition frees limited working memory resources for resource-draining reading comprehension skills. Automaticity of handwriting and spelling skills frees limited working memory resources for the constructive processes of text generation. Automaticity of math fact retrieval and application of computational algorithms (e.g., Ackerman, Anhalt, & Dykman, 1986; Garnett & Fleischner, 1983) frees limited working memory resources for resource-draining higher-level thinking skills in math problem solving (Hiebert et al., 1996; Jordan & Montani, 1997). Thus, one instructional goal for all academic domains should be to develop automaticity of low-level skills (e.g., word recognition, spelling, and math fact retrieval and computation). At the same time, another instructional goal for all academic instruction should be facilitation of higher-level thinking skills where students construct and apply knowledge and metacognitive strategies (e.g., reading comprehension, written composition, and math problem solving).

Fuchs, Fuchs, Phillips, Hamlitt, and Karns (1995) make the important point that different teaching methods may be effective in teaching the low-level and high-level skills. Students may benefit from instructional integration of these different methods. One of the general principles supported in our programmatic research on instructional intervention in reading and writing is that teaching low-level and high-level skills *close in time* within the same lesson facilitates transfer of the low-level skills (the tools) to improved high-level skills (the goal). Much of the unfortunate bickering among educational professionals over phonics versus whole language in reading, basic skills versus the process approach in writing, and basic skills versus the problem-solving approach in math has common themes and could have been avoided if this general principle of balance between low-level and high-level skills had been more widely understood. However, balance across the school day between teaching low-level basic skills to automaticity and encouraging high-level constructivist thinking may not be sufficient for integrating low-level and high-level skills in functional reading and writing systems. How these instructional components are packaged within lessons *close in time* may also be important, especially for students who struggle in academic skill acquisition. Berninger (1998a) contains greater elaboration on these general principles, their research support, and their educational implications for assessment and intervention practices.

Alternative Assessment Instruments

Just as there is more than one way to learn a skill and to teach a skill, there is more than one reliable and valid way to assess an academic skill. Berninger (1998a, Chapter 4) described alternative instruments for tier 1 and tier 3 assessment of each of the skills in the functional reading and writing systems. Berninger, Stage et al. (2001) reviewed the various curriculum-based measures that various research groups have developed and school psychologists throughout the country are using for tier 2 assessment. These are important as fluency metrics because many students' reading and writing problems are not apparent on tests that assess only accuracy and are evident only under timed conditions (Berninger, Abbott, Billingsley, & Nagy, 2001). Busse et al. (2001, Table 1) listed alternative instruments for assessing specific math skills in the functional math system. Various chapters in Andrews, Janzen, and Saklofske (2001) are resources for additional test instruments and assessment procedures for reading, writing, and math. Multi-modal assessment with a variety of instruments and assessment procedures is desirable (Berninger, 1998a, Chapter 10). See the PAL Intervention Guides for processes and skills to assess and suggestions as to which alternative tests might be used to assess each process or skill. What is important is not that a specific test is used but rather that all the empirically supported processes and skills be assessed, using any research-validated measure, and taught, using any effective instructional method.

Accountability

Increasingly, school psychologists are being asked to play a role in demonstrating accountability in terms of student learning outcomes. Chapter 10 of the *PAL Intervention Guides* outlines how multi-modal assessment, including criterion-referenced, curriculum-based, norm-referenced, and portfolio-based approaches, can be used for this purpose. School psychologists may apply these options in varied ways that are suited to their school setting.

EMPIRICALLY SUPPORTED BEST PRACTICES IN ASSESSING AND TEACHING ACADEMIC SKILLS META-ANALYSES

Swanson, Hoskyn, and Lee (1999) conducted meta-analyses on instructional intervention research from which seven themes emerged. First, on average, the largest size effects were found for reading comprehension (.81) and vocabulary (.73), modest size effects were found for word recognition (.65) and phonics (.60), and the smallest size effects were found for spelling (.51) and handwriting (.53). Second, the most effective interventions combined direct instruction and strategy instruction components, and group plus one-to-one instruction yielded higher effect sizes than one-to-one instruction alone. Third, the combined direct instruction and strategy instruction was more effective for reading in general and reading comprehension in particular, whereas direct instruction alone was more effective for word recognition. Fourth, there was further evidence of domain-specific treatment effectiveness. Effect sizes for word recognition were higher when an instructional component involving segmentation of words was present. Effect sizes for reading comprehension were higher when teachers explicitly modeled comprehension strategies. Effect sizes for spelling were higher when lessons were sequenced and involved segmentation. Effect sizes for writing were related to orientation to task. Effect sizes for math were related to instruction in small, interacting groups. Fifth, differences between students with and without learning disabilities were smaller when treatments included strategy instruction. Sixth, intelligence scores predicted effect sizes when reading was severely disabled or in the average range but were less predictive when reading was only mildly deficient. Seventh, the effect sizes for direct instruction (.82) and for strategy instruction (.84) were comparable.

The National Reading Panel (National Institute of Child Health and Human Development, 2000) concluded on the basis of research that met rigorous criteria for quality control that essential components of reading instruction are phonological awareness, letter knowledge, word decoding, fluency, and comprehension. A full report of this panel and an accompanying video are available from the National Institute of Child Health and Human Development. School psychologists can use this material in conducting in-service workshops for other school personnel.

Meta-analyses are not available with a specific focus on only writing or math interventions for students with learning problems specific to these academic domains. However, Berninger (1998a) reviewed the results of cross-sectional studies of writing skills of 900 students in grades 1–9. Handwriting, spelling, and composition were shown to be interrelated but separable skills that need to be assessed independently but taught in a coordinated, integrated fashion to students with written expression problems. Also, Busse et al. (2001) reviewed research supporting the long-standing distinction among fact retrieval, computational algorithms, conceptual knowledge, and problem solving in the math domain, which are skills that need to be assessed and taught in a coordinated, integrated fashion to students with math problems.

Recommended Assessment and Intervention at Each of Three Tiers

Table 1 refers school psychologists to other sources that outline skills and possible assessment instruments for each of the three tiers aimed at organizational change in delivery of assessment and intervention services. These sources also contain information on related instructional interventions. In the section that follows, additional information is provided for instructional resources for each academic domain.

Table 1. Recommended assessments for reading, writing, and math at each tier

Reading		
	Tier 1	See Table 1 in Berninger, Stage et al. (2001) and Berninger (2001).
	Tier 2	See ACES (Di Perna & Elliot, 2001) and Table 6.1 in Berninger (1998a).
	Tier 3	See Table 7.1 in Berninger (1998a), Table 3 in Berninger, Stage et al. (2001), and Berninger (1998a, 2001).
Writing		
	Tier 1	See Table 2 in Berninger Stage et al. (2001).
	Tier 2	See Table 6.2 in Berninger (1998a).
	Tier 3	See Table 7.1 in Berninger (1998a), Table 3 in Berninger et al. (2001), and Berninger (2001).
Math		
	Tier 1	See Table 2 (top two rows) in Busse et al. (2001).
	Tier 2	See ACES (Di Perna &Elliott, 2001) and Table 2 (third row) in Busse et al. (2001).
	Tier 3	See Table 2 (bottom row) and Table 1 in Busse et al. (2001).

Note: Space limitations preclude reproduction of each of the tables. The tables specify both which skills to assess and which test(s) might be used for each skill (that is, both the why and how of assessment). These tables are in publications widely available to school psychologists.

Reading

TIER 1

See Table 1 for resources for tier 1 screening. Researchers have developed assessment instruments that have been validated for Tier 1 screening. These include the *Texas Primary Reading Inventory* (Texas Education Agency, 2000), the *PALS: Phonological Awareness Literacy Screening* (Invernizzi, Meier, Swank, & Juel, 2000), and the *Process Assessment of the Learner Test Battery for Reading and Writing (PAL-RW)* (Berninger, 2001). Subtests of the Third Edition of the Woodcock Psychoeducational Achievement Battery and the Second Edition of the Wechsler Individual Achievement Test (see Andrews et al., 2001) can also be used for this purpose. Likewise, research-based fluency measures such as Dynamic Indicators of Basic Early Literacy Skills (DIBELS) (e.g., Kaminsky & Good, 1998) can be used for this purpose. What is more important than which test is used is that all the processes that research has shown are the best predictors of beginning reading and writing are assessed at the developmentally appropriate time. Berninger, Stage et al. (2001) and Berninger (2001) list these at different grade levels for both reading and writing.

Several large-scale research studies have shown the importance of explicit training in phonological awareness and phonological decoding (i.e., code instruction) in early intervention to prevent reading disabilities (e.g., Foorman, Francis, Fletcher, Schatschneider, & Mehta, 1998; Torgesen et al., 1999; Vellutino, Scanlon, & Tanzman, 1998). School psychologists might provide consultation to text book adoption committees in their school districts to ensure that instructional materials are used that provide explicit code instruction to all students who for whatever reason are identified as being at-risk in reading through tier 1 screening. Children whose parents have had little formal education and provide few home literacy experiences and whose families have a positive history of reading disability are especially likely to benefit from explicit code instruction. Examples of classroom programs that provide explicit code instruction include but are not restricted to *Open Court*, *Success for All*, and *Distar*. Empirically supported early intervention program for phonological awareness and phonological decoding training that can be used in the general education program with large groups or pull-out early intervention programs for smaller groups include the following: (a) the American version of the Lundberg's Swedish program (Adams, Foorman, Lundberg, & Beeler, 1998), (b) *Ladders to Literacy* (Notari-Syverson, O'Connor, & Vadasy, 1998), (c) *Road to the Code* (Blachman, Ball, Black, & Tangel, 2000), (d) *Sound Partners* (Jenkins, Vadasy, Firebaugh, & Profilet, 2000), and (e) *Talking Letters* (Berninger, 1998b; Berninger et al., 2000). An appropriate education for any student flagged on tier 1 assessment should include one of these or a comparable empirically supported program. In addition, *Words Their Way* (Bear et al., 1996) has activities and games that reinforce explicit code instruction and encourage use of multiple strategies in word learning. Multiple strategies are important for developing executive functions for self-regulation of the process of learning to read and write words.

Not only accuracy but also rate should be assessed for single-word reading and for text reading. Curriculum-based measurement is ideally suited for assessing rate (efficiency) of component skills. Although standardized, nationally normed measures have traditionally assessed only accuracy of academic skills, recently such standardized measures have been developed for assessing rate of single-word reading, rate of oral text reading, and rate of reading comprehension (see Andrews et al., 2001). Many standardized and curriculum-based measures now contain measures of rapid automatized naming (RAN), which are excellent predictors of reading rate. The *Read Naturally Series* (Read Naturally, 1997) is a commercially available individualized program for developing oral reading fluency (and transfer to comprehension) through repeated readings and wide reading of high interest material at a student's instructional level and graphing of cold (initial) and hot (subsequent) reading rates and performance on comprehension measures. *Great Leaps Reading* (Mercer & Campbell, 1997) is another commercially available resource for developing reading fluency. Although practice in reading a wide variety of texts or the same text repeatedly may be sufficient for some students to become fluent, others may need specialized techniques for developing automatic word recognition (e.g., rate training for automaticity of alphabet principle) or training in metacognitive strategies for self-regulation (Berninger, Abbott, et al., 2001).

845

A variety of informal and standardized techniques can be used to screen reading comprehension, including the cloze technique for supplying the missing word in text, question answering (multiple choice or open ended), and story retell. Early in literacy acquisition, these various measures load on the same factor in at-risk readers (Berninger et al., 2000), and any of them can be used to screen for and monitor progress in reading comprehension. However, comprehension should not only be monitored early in reading acquisition but it should also be taught explicitly, just as the code needs to be taught explicitly. The *PAL Intervention Guides* list commercially available instructional resources for reading comprehension that can be used in the general education reading program or supplementary early intervention outside the regular classroom.

Tier 1 assessment-intervention links can be effective in helping children overcome the Matthew Effect, whereby initially good readers become better readers (richer) and initially poor readers become poorer readers (poorer), as illustrated by the following example reported by Berninger (1999). In one school that adopted a systems-level intervention to improve literacy, all first and second grade classroom teachers and the special education teacher taught reading during a 2-hour language arts block at the beginning of each day. School psychology interns assessed all students at the beginning and end of the school year, and America Read tutors worked individually with students to provide additional experience in reading to an adult. During the language arts block, explicit reading instruction was provided in groups that drew from all first and second grade classrooms and were not defined by grade placement. Rather, groups were defined by instructional level as determined by informal reading inventories, which were administered at the beginning of the year and re-administered during the year if teachers suspected an individual student's instructional level had become significantly higher or lower than that of other children in the group. If appropriate, changes in group placement were made. The special education teacher taught the group of first graders who tested the lowest at the beginning of the year, but because the language arts instruction was delivered at the same time for all children and in regular classrooms (not special rooms for pull-out), these children did not perceive themselves to be receiving anything different in reading than their peers did. These children who began first grade as the lowest readers received an instructional program containing all the components recommended by the National Reading Panel (National Institute of Child Heath and Human Development, 2000): phonological awareness, explicit phonological decoding, fluency training (repeated reading of the same texts and wide reading of many different texts), and comprehension. Children also received all the necessary components of writing instruction, including handwriting automaticity training, sequenced spelling lessons, and composing activities (Berninger, 1998a, 1998b). They also received integrated listening-writing-reading activities and were encouraged to be active, reflective learners who asked questions and who derived joy from reading and writing.

The nine children who started out the lowest in reading had standard scores for age that were delayed both for their average verbal IQs and grade placement at the beginning of first grade on Woodcock Reading Mastery-Revised (WRMT-R) Word Identification (WI) (M = 83.9, SD = 11.2, 15th percentile) and Word Attack (WA) (M = 69.7, SD = 6.8, 2.5 percentile). By the end of first grade, their average standard scores for age had not only increased beyond the mean (WI, M = 107.7, SD =15.2, 70th percentile; WA, M = 106.3, SD =10.1, 64th percentile) but were also comparable to the average scores of all the first grade children in this school at the end of the year. This empirically supported demonstration of student learning outcome shows that a systems level intervention can be effective in overcoming the Matthew Effect.

TIER 2

See Table 1 for resources for tier 2 assessments. An integrated system for assessing students having difficulty in the general education classroom at any grade level (K–12) and for planning, implementing, and evaluating pre-referral interventions is the *Academic Competence Evaluation Scales* (ACES) (Di Perna & Elliott, 2001), which has been empirically validated. ACES assesses both academic skills and academic enablers (interpersonal skills, motivation, study skills, and engagement). Teachers rate each item on frequency of occurrence over the past month and the importance in their classroom of behaviors, skills, and activities for 11 reading/language arts items. Students with at least a fourth grade reading level also rate themselves on the same items. To foster home-school communication and collaboration, parents also rate their children. These ratings are used to identify concerns (step 1) and analyze concerns (step 2). The related *Academic Intervention Monitoring* (AIMS) (DiPerna, Elliott, & Shapiro, 2001) is a guidebook for selecting and planning (step 3) and implementing (step 4) classroom-based interventions for difficulties in academic skills and academic engagement. ACES can be re-administered to monitor and evaluate progress and demonstrate student-learning outcomes.

Curriculum-based measures are also ideally suited for progress monitoring. These are typically timed and therefore especially suited for monitoring the development of reading fluency skills (Berninger, Abbott et al., 2001). However, un-timed curriculum-based measures could also be constructed by using curriculum materials for other components of reading curriculum that the National Reading Panel found to be essential in beginning reading instruction, such as phonological awareness, phonological decoding of unknown words, sight word vocabulary, and reading comprehension. Informal reading inventories are one approach to this kind of curriculum-based assessment and can be constructed by using textbooks and other instructional materials used in the general education classroom to monitor progress. Classroom observations and teacher interview (Shapiro, 1996) are other ways to monitor student progress, as well as assess if all the necessary components of the reading curriculum (Berninger, 1998, Table 6.1) are available to the student.

TIER 3

See Table 1 for resources for step-by-step differential diagnosis for specific reading disability. Some students do not respond or respond very slowly to tier 1 or tier 2 intervention. In such cases these students should be given a comprehensive assessment for three purposes: (a) to evaluate whether they qualify for special education services, (b) to diagnose why they are struggling in reading, and (c) to plan a more intensive, integrated intervention that includes all the necessary instructional components but is individually tailored to specific areas of weakness. Many parents desire a diagnosis whether or not their child qualifies for special education, and making a diagnosis can have a beneficial effect on home-school relationships in many cases. The *PAL Intervention Guides*, which elaborate on the rationale for tier 3 assessment that goes beyond special education placement decisions, describe a model for differential diagnosis based on developmental domains and axes that are more appropriate to educational diagnoses in school settings than those used for psychiatric diagnoses in medical settings. The *PAL Intervention Guides* also include individual education planning forms for reading, organized by all the necessary components of reading instruction, which can be used in educational planning, teaching, and progress monitoring, whether or not a student qualifies for special education. The forms can be used in conjunction with the list of commercially available resources that is also organized by the necessary components of reading instruction.

Writing

TIER 1

See Table 1 for resources on which skills to include in tier 1 screening for writing. The *PAL Guides for Intervention Kit* (Berninger, 1998b) contains empirically supported handwriting lessons and instructional materials for spelling that can be used for tier 1 intervention.

TIER 2

See Table 1 for resources for assessing whether the necessary components of writing instruction are present and for generating instructional interventions. Portfolios (Valencia, 1998) are especially important in monitoring writing progress when children are given pre-referral interventions in writing.

TIER 3

See Table 1 for resources in making step-by-step differential diagnoses in specific writing disabilities. Children who do not respond or respond very slowly should be given a thorough diagnostic assessment. As with reading, the purpose of this tier 3 assessment is threefold: (a) to evaluate whether a student qualifies for special education services, (b) to pinpoint the nature of any writing disability, and (c) to plan individually tailored, but comprehensive, integrated instruction aimed at all the necessary components of a functional writing system. The *PAL Intervention Guides* include individual education planning forms for writing, which are organized according to all the necessary components of writing instruction and

847

yoked to the list of commercially available resources that are also organized by these necessary components. Our experience has been that some students have both talents (e.g., composing) and disabilities (e.g., transcribing because of handwriting and/or spelling problems) in the writing domain, and educational planning needs to be directed to both their strengths and weaknesses.

Math

TIER 1

See Table 1 for resources for tier 1 screening for both math talent and math disability. Some students have talents in specific math skills while simultaneously having a disability in another math skill. When talent and/or disability is identified, school psychologists should help design intervention to nurture math talent and/or to prevent math disability.

TIER 2

See Table 1 for resources for tier 2 assessment. ACES (Di Perno & Elliott, 2001) contains eight math items. Teachers, students (with grade 4 reading ability and higher), and parents rate these items to identify students needing pre-referral intervention. AIMS (Di Perno, Elliott, & Shapiro, 2001) can be used to generate and implement math interventions. ACES can be re-administered to monitor progress and document student-learning outcome in the math domain.

TIER 3

See Table 1 for resources for comprehensive assessment of math skills. As in the other academic domains, some students will not respond or will respond very slowly to early intervention or pre-referral intervention in math. These students should be given a comprehensive diagnostic assessment to evaluate whether they may qualify for special education or gifted programming (or both), to pinpoint any areas of math talent or disability, and to plan accordingly for instructional interventions. See Busse et al. (2001) for interventions for both math precocity and math disability.

SUMMARY AND CONCLUDING REMARKS

School psychologists are encouraged to move beyond their traditional individual assessment role in serving students with academic skills problems. Instead of testing students one at a time and consulting with one teacher at a time, school psychologists should actively work, along with other professionals on the team, toward organizational change aimed at preventing academic skills problems or at least reducing their severity. In this chapter a 3-tier model is described for achieving such organizational change. In tier 1, school-wide screenings are conducted to identify students who have deficits or are at risk in reading, writing, and/or math. Early intervention programs are planned, implemented, and evaluated. In tier 2, pre-referral assessment of students' classroom functioning and of curriculum is followed by pre-referral intervention in which the regular program is modified, the students' progress is monitored, and interventions are modified if progress is not made. In tier 3, comprehensive diagnostic assessments are conducted for those students who did not respond or responded very slowly to early intervention or pre-referral intervention. The goal of tier 3 is not only to evaluate whether students qualify for special education services but also to diagnose the nature of their reading, writing, and/or math problems and to plan interventions aimed at all the necessary components of functional reading, writing, and math systems. At all tiers the assessments and interventions should be based on scientific research. School psychologists can also be catalysts for organizational change in the academic domain by conducting continuing education workshops for other professionals in their school system and local buildings, by advising the school system on curriculum issues such as text book adoptions, and by consulting on educational measurement and assessment issues.

This chapter contains many recommended resources for school psychologists to update their knowledge of academic assessment and intervention and to draw upon in practice. For school psychologists who wish to keep up with rapidly expanding research developments in the academic domain, the list of journals at the end of the chapter is representative of the journals that publish research on academic assessment and intervention, much of which does not appear in school psychology journals. To conclude, both pre-service and in-service school psychologists who participated in the intervention and assessment studies of the University of Washington Multidisciplinary Learning Disabilities Center, which included a systems-level intervention aimed at organizational change, have shared the following observation. Professional practice grounded in assessment-intervention links that results in empirically documented student learning outcomes can be more professionally rewarding than merely assessing academic functioning of one student at a time and leaving the academic intervention solely to other professionals on the team.

Berninger, V. (1998a). *Process assessment of the learner (PAL): Guides for reading and writing intervention.* San Antonio, TX: The Psychological Corporation.

Berninger, V. (1998b). *Process assessment of the learner (PAL): Intervention kit.* San Antonio, TX: The Psychological Corporation.

Berninger, V. (2001). *Process assessment of the learner: Test battery for reading and writing (PAL-RW).* San Antonio, TX: The Psychological Corporation.

These three related resources provide an integrated system for assessment (Berninger, 2001) and intervention (Berninger, 1998a, 1998b) for reading and writing that is based on research on reading and writing supported by the National Institute of Child Health and Human Development. It is not designed as a stand-alone assessment system but rather as an assessment approach to be integrated with many other nationally normed standardized tests as well as curriculum-based, criterion-based, and portfolio-based measures for purposes of preventing and treating reading and writing problems in school systems as well as in individual students. Likewise, it offers a conceptual approach, which is grounded in research on instructional intervention and assessment-intervention links, that encourages psychologists and teachers to draw on a variety of instructional methods and materials for helping students develop functional reading and writing systems.

55 Best Practices in the Assessment of Written Expression

Scott Baker
Eugene Research Institute and the University of Oregon
Dawn Hubbard
Northeast Kansas Education Service Center

OVERVIEW

Connelly (1983) noted that "education is inextricably linked with the capacity to produce visible language" (p. xi). What good writers do, as captured in this description by Butler, Elaschuk, and Poole (2000), indicates why writing is such an important educational goal as well as a vehicle for helping students learn and practice important learning strategies and skills:

> Effective writers are self-regulating . . . . They analyze task requirements, articulate writing goals, and then select, adapt, or even invent strategic approaches to achieve their objectives. They monitor the success of their efforts as they engage recursively in planning, text production, and editing activities. If obstacles are encountered, effective writers adaptively adjust goals . . . or writing strategies (p. 195).

Two compelling reasons justify a chapter for school psychologists devoted to the assessment of written expression. First, many students are not acquiring even rudimentary written expression skills. Second, there is a considerable body of high quality research pointing to effective writing approaches and interventions for students with written expression problems.

According to latest results of the National Assessment of Educational Progress (National Center for Education Statistics, 1998) 16% of fourth-grade students, 16% of eighth-grade students, and 22% of twelfth-grade students were not able to write at even the most basic level. Writing problems surface early and in many cases remain with students through the duration of their formal educational experiences (Isaacson, 1995). In addition, written expression in the early grades is a good predictor of overall school success, and in many cases becomes the first indication of academic difficulty noticed by teachers (Isaacson, 1995).

Along with reading problems, written expression problems constitute the greatest number of referrals to, and placements in, special and remedial education programs (Hallahan & Kauffman, 1986; Howell, Fox, & Morehead, 1993). On every conceivable measure of writing performance, students with learning disabilities, for example, write much more poorly than do students without disabilities (Englert, Raphael, Anderson, Anthony, & Stevens, 1991; Graham, Berninger, Abbott, Abbott, & Whitaker, 1997). In essence, when students with learning disabilities write, they pay little attention "to the needs of the audience, the organization of text, the development of rhetorical goals, or the constraints imposed by the topic" (Graham & Harris, 1997, p. 414).

The second reason school psychologists should have a strong understanding of issues involved in writing instruction and assessment is that over the past 15 years innovative research has developed exciting new methods for teaching students to write more effectively (Englert et al., 1991; Graham & Harris, 1989; Wong, Butler, Ficzere, & Kuperis, 1996). This research, conducted primarily by special education researchers, has explored ways to teach students how to analyze material learned in the classroom and to write both personal narratives, based on students' own interpretations of life experiences, and persuasive essays, in which students take positions on topical social and political issues. Stimulated by studies in reading comprehension, research in expressive writing has increasingly taken on a life of its own. In the past 10 years, it has surpassed reading comprehension research in breadth of coverage as well as instructional implications for improving classroom practice (Gersten & Baker, 2001).

This research has slowly begun to be translated into classroom practice. Teachers are moving away from instruction that focuses exclusively on the mechanics of writing to instruction that focuses on the range of tasks involved in the writing process (Raphael & Englert, 1990). Teaching students to be better writers is a challenging and worthwhile instructional objective. To write well requires that students have an adequate knowledge base from which to draw content ideas, the skills to organize their ideas and present them in print according to established conventions, and sufficient self-monitoring strategies to guide the recursive writing process (Gersten & Baker, 2001). School psychologists need assessment procedures that reflect the richness and complexity of the written expression process.

Several reasons for the recent emergence of high-quality research in written expression will help school psychologists understand how to approach adequately assessing written expression (Gersten & Baker, 2001). Straightforward interest in developing methods for teaching students with learning disabilities to express their own ideas was influential from the beginning. Writing is an excellent vehicle for expressing personal perspectives and opinions and serves a legitimate academic purpose. Even factual expository writing allows students to demonstrate their unique perspectives on, and understanding of, social, political, and historical issues.

A shift in thinking also helped spur the rapid growth of research in expressive writing instruction. Evidence suggested that the academic strengths of students with learning disabilities could be demonstrated and enhanced more effectively if writing instruction focused less on mechanics (e.g., legibility and punctuation) and more on content. Goldman, Hasselbring, and The Cognition and Technology Group at Vanderbilt University (1997) summarized the research by observing that, "when asked to write about complex ideas, students with learning disabilities often demonstrate conceptual performance that far exceeds what would be predicted based on their performance on lower level skills such as capitalization, punctuation and spelling" (p. 203).

Writing instruction also was viewed as a means to help students understand critical linkages between reading and writing (Englert, Raphael, & Anderson, 1992; Graves, 1978, 1983). It was demonstrated that teaching students about how texts were structured improved reading comprehension. It made sense to build on what students learned about text structure by having them work with it in their own writing assignments. Students learned that they could use the major elements of the stories they read—characters, settings, and problems, for example—in their own stories to make them more enjoyable to read, and to write.

A final reason for the increased focus on expressive writing research is more speculative than the others. It may be that written expression is somewhat easier to assess than reading comprehension (see, e.g., Kucan & Beck, 1997). Products of writing ability are easier to collect than products of reading comprehension, thus making it easier for assessment experts to work on developing tasks that not only meet traditional criteria for reliability and validity but also satisfy current conceptualizations regarding the importance of assessment authenticity. In fact, the measures used in expressive writing research have often served as models in state writing assessments.

BASIC CONSIDERATIONS

One goal of this chapter is to provide a framework for assessing written expression that is adaptable to the diverse writing expectations and formats that characterize classroom settings. In pursuit of this objective, two assumptions are made that serve to structure the assessment of written expression. First, assessment procedures should be guided by a decision-making purpose, and the data collected should reflect that purpose (Deno, 1989; Salvia & Ysseldyke, 1981; Shinn & Hubbard, 1993; Shinn, Nolet, & Knutson, 1990). In this context, the purpose and relevance of assessment data should be clear to the teachers, parents, and students who may be affected by the outcome. The second assumption is that comprehensive assessment procedures should address not only student writing performance but also the environmental variables that may be contributing to writing problems, and that serve as intervention targets.

Before addressing specific aspects of assessing written expression, sources of data and measures that are useful for those purposes, and a decision-making context in which assessment activities are embedded, we want to provide an overview of instructional conditions that have been demonstrated to lead to improved writing performance. If school psychologists have a strong understanding of which instructional factors can be expected to best lead to better writing outcomes, then their assessments will be richer, more focused, and more likely to lead to interventions that improve student writing performance.

Changes in Traditional Classroom Writing Instruction

Writing instruction in traditional classroom environments frequently focuses on student adherence to writing conventions such as spelling, punctuation, grammar, and handwriting (Englert & Mariage, 1992). In the early elementary grades, the focus tends to be on punctuation skills (Bridge & Hiebert, 1985). During later elementary grades, more attention is directed toward copying activities, improving punctuation skills, and developing proficiency in identifying parts of speech (Bridge & Heibert, 1985). At the secondary level, the focus tends to be primarily on the completion of grammar exercises (Applebee, 1991).

Research has long demonstrated that focusing on writing conventions and grammar does not result in overall improvements in students' written compositions (Englert & Mariage, 1992; Hillocks, 1984; Isaacson, 1987). Furthermore, research conducted over the past decade has provided a clear roadmap for what writing instruction should look like in classrooms across the country. Much of this research has been reviewed in a meta-analysis on writing intervention studies conducted by Gersten and Baker (2001).

Gersten and Baker (2001) (portions of the section describing the meta-analysis were adapted from Gersten and Baker (2001)) concluded that when classroom instruction includes certain innovative instructional components, rather than traditional writing instruction methods, there is considerable benefit for students with writing problems as well as students who are good writers. Studies with innovative components showed consistent increases in the quality of written products, and effect sizes were moderate to large in magnitude (the mean effect size was .81 across 13 group design studies). These components produced positive outcomes across writing genres (e.g., comparison essays versus narrative stories) and across procedures used to assess quality (e.g., global ratings of quality versus the sum of scores for individual writing traits or rubrics). Also, these components had a moderately positive impact on students' understandings of the writing process. There was some evidence that student attitudes about writing and student feelings about themselves as writers also improved.

The vast majority of writing intervention studies included components that were grouped into three main categories: (a) explicit teaching of critical steps in the writing process, (b) explicit teaching about text structures and how they can be used in compositions, and (c) providing students with ongoing feedback on the quality of their writing. It is our experience, however, that with few notable exceptions, these components are rarely implemented adequately in either general or special education classrooms, and the combination of the three, which we believe would provide the foundation for an excellent instructional program in written expression, is rarely used. Nevertheless, increasing interest in these approaches is likely as teachers and other practitioners learn more about the research base, and as more students with disabilities take state assessments, which typically include a writing component (Gersten & Baker, 2001).

Explicit Instruction in the Writing Process

Writing intervention studies that addressed the writing process used a framework that included some variation of three essential steps: planning, writing, and revising. Invariably, explicit teaching of each step was provided by the teacher through several examples, often supported by a "think sheet," a prompt card, or a mnemonic.

Teaching students to write requires showing them how to develop and organize what they want to say and guiding them in the process of getting it down on paper. The plans students develop are critically important. To help students conceive and effectively use a "plan of action," teachers, or competent peers, should verbalize the steps they take when they engage in the writing process.

It helps when plans of action are visible to students and easy for them to understand and refer to as they work. Effective plans provide students with a concrete map for engaging in the writing process, and they provide suggestions for what students should do when they feel stuck or overwhelmed. Concrete plans also provide a common language that teachers and students can use to focus and enhance the quality of dialogue they might have about writing tasks and assignments. We believe this dialogical function represents a major advance of writing instruction over traditional methods, which required students to work in relative isolation when they wrote.

Well-developed plans result in better first drafts. Revising and editing skills are also critical to the writing process. Developing methods to help students with writing difficulties refine and edit their work has proved challenging. However, a few researchers have begun to develop specific strategies that appear promising (e.g., Englert et al., 1991; Harris & Graham, 1992; MacArthur, Schwartz, & Graham, 1991; Schumaker, Nolan, & Deshler, 1985; Wong et al., 1996). The use of peer editing, for instance, is an integral and recurrent strategy in the research of Englert, Wong, and MacArthur.

In assessing the writing environment, school psychologists should document, through interviews with the teacher and through direct observation, the extent to which explicit instruction is provided for each stage of the writing process. In many classrooms, the focus will be primarily on actual composition; that is, generating a writing product that adheres to established conventions. Typically, little instruction will be directed toward how to generate and organize ideas for writing, or how to improve a written product through revision.

Englert and her colleagues (Englert & Mariage, 1992; Englert & Raphael, 1989) have documented the effectiveness of explicitly teaching the stages of the writing process. For example, Englert and Mariage taught students a mnemonic to help them learn to plan, organize, write, edit, and revise (POWER) their written products. Teachers first modeled each stage of the writing process by "thinking aloud." In modeling planning, for example, teachers used self-talk and other overt procedures to clearly identify their audience and the purpose for writing. To activate background knowledge teachers modeled brainstorming strategies to generate writing ideas, and how to organize those ideas for content inclusion during the transcribing stage. Then they worked with students to write a class paper using the POWER strategy. Over time, students assumed more and more control of the writing process. Eventually, each student was required to complete a writing project independently and demonstrate mastery of each stage of the writing process.

Explicit Instruction of Writing Genre Conventions

Different writing genres rely on specific text conventions unique to that style to establish the basic structure or framework for the composition. A persuasive essay, for example, contains a thesis and supporting arguments; that is, elements that differ considerably from those found in narrative writing. Awareness that written text involves recurring structures and patterns is an important prerequisite to mastering the writing process (Englert & Mariage, 1992). In many classrooms, students will be expected to develop writing skills to match different types of text structures. School psychologists should be familiar with the components of different text structures as they assess environmental variables that may be affecting student performance. For example, students may be expected to write proficiently by using narrative text structure as well as many types of expository text structures such as compare/contrast, description, explanation, and persuasion (Englert & Mariage, 1992).

Explicit teaching of text structures provides a useful guide for undertaking a particular writing task. Good instruction typically includes numerous explicit models and prompts. Greater levels of specificity provided by the prompts appear to be associated with better written products (Gersten & Baker, 2001).

Concrete maps and organizers make writing using text structures visible to students and help keep them focused on important genre conventions (e.g., Englert et al., 1992, 1991). Students begin to recognize the sameness, or reoccurring text patterns, which they can use to guide their "efforts to produce well-organized texts and fuel their ability to interpret, monitor, and talk about texts" (Englert & Mariage, 1991, p. 333). De La Paz and Graham (1997) showed clearly that these types of concrete structures were critical to the completeness and overall quality of expository essays produced by students with learning disabilities.

Narrative text structure is one of the earliest text structures acquired by children and contains a number of standard components (Englert & Mariage, 1992). Typical story grammar elements in narrative text include setting events, episodes, and conclusions. In some classrooms, teachers may expect students to include story grammar elements in the students' writing without providing explicit instruction on how that is done. In other classrooms, explicit instruction may occur on as many as eight or more elements (Simmons et al., 1994).

The organizational approach used to construct a narrative is not, in and of itself, what makes a story engaging. Rather, good writing involves utilizing what Englert et al. (1991) call "overlapping and recursive processes" (p. 364). These processes do not proceed in a particular order, and one process may inform another in such a way that the author returns to previous steps for update or revision on a regular basis (Gersten & Baker, 2001).

Many students become implicitly aware of story grammar elements before they begin school, primarily through story reading at home. Yet at the high school level, many low achieving students do not have a basic understanding of story grammar elements and, not surprisingly, the writing these students produce tends to be extremely poor in comparison with their classroom peers (Graves, Montague, & Wong, 1990; Meyer, Brandt, & Bluth, 1980). Recent developments in integrated curricula highlight one way to teach text structure elements in the context of written expression that may be useful in planning instructional programs (Langer & Applebee, 1987). For example, in an integrated reading and writing curriculum, students might learn about story grammar elements during reading instruction and then integrate those elements into their own written compositions (Raphael & Englert, 1990).

A study by Graham and Harris (1989) includes a number of components for planning instructional programs that meet the needs of students with poor writing skills. For example, Graham and Harris taught students a question asking strategy to improve their narrative writing. Their program began with pre-writing activities that focused on identifying and generating story grammar elements using a mnemonic for seven story grammar questions. After students were able to recite the mnemonic and discuss its meaning, they generated story grammar elements while looking at a picture. A five-step learning strategy was used to help students write stories by using the picture prompt. The teacher first demonstrated the strategy by using a "think aloud" technique. Students then practiced the five-step learning strategy as they wrote their own stories independently. In providing feedback to students, the stories were read by the teacher and students as a group, and if any of the story elements were missing, the group discussed how and where they could be added. The stories were returned to the students for revision based on teacher and student recommendations.

Guided Feedback to Promote Writing Development

The third component that emerged in the meta-analysis on effective writing was guided feedback (Gersten & Baker, 2001). Either teachers or peers provided frequent feedback to target students on the overall quality of their writing, missing elements, and strengths. When feedback was combined with instruction on the writing process or text structure, a common vocabulary was created that gave teachers and students a meaningful way to engage in dialogue, which resulted in improved written products. The prompts helped give teachers or peers concrete suggestions for providing appropriate feedback. With the benefit of such feedback, students demonstrated what Englert et al. (1991) called "reader sensitivity," and what others refer to as writing style. In other words, students began writing in a way that was not only clear and factually correct, but also engaging for readers, because the style began to take into account reader expectations and ways to keep the reader engaged.

Some of the successful approaches set up elaborate systems for peer feedback and review (Englert et al., 1991; MacArthur et al., 1991; Wong et al., 1996; Wong, Butler, Ficzere, & Kuperis, 1997). Wong et al. (1997), for example, used guided interactive dialogue between peers, first to engage target students in the process of preparing a comparison essay, and then to assist them in revising their first draft. De La Paz and Graham (1997) demonstrated the importance of interactive dialogue between the teacher and student, who together focused on key components of the writing strategies. Wong and her colleagues hypothesized that interactive dialogues, which lead students through multiple cycles of reflection, realization, and redress of problems, helped them "see" their thoughts and write from another's perspective.

In all cases, concrete organizers were used to help initiate and focus dialogue about a writing task. Wong et al. (1996) modeled procedures for students and teachers to use in providing feedback so that they would attend not only to the surface features of writing (i.e., spelling, punctuation) but also to the presentation of ideas. The central feature of guided feedback seemed to be that teachers and peers had an organizational framework and a language to use in providing feedback to target students about their attempts at organization, originality, and interpretation.

The question of whether the teacher or peers should provide feedback may be less crucial than the quality of the feedback provided. In one study by Wong et al. (1996), teacher feedback was compared specifically to peer feedback, and the result was that both sources of feedback had a strong positive affect. What appears to be most important is that elaborate and explicit systems are set up for giving feedback (Englert et al., 1991; Wong et al., 1996).

Any strong instructional program for teaching students to communicate effectively through written expression should be linked to summative and formative measures to assess student progress. Formal methods of assessing written expression will be used by school psychologists and other specialists to help determine if students have disabilities that may be interfering with progress. Teachers also need ways to assess student writing that, though not as comprehensive as those used by a school psychologist, are still capable of providing information to determine how much progress students are making, and areas that require further instruction and practice. In the next section we detail methods of assessing written expression.

BEST PRACTICES IN ASSESSING STUDENT WRITING

Assessing Written Expression Within a Decision-Making Context

Best practices in assessing student writing performance should focus on gathering meaningful data within a problem-solving framework, which drives the process that leads to sound and reasonable decisions (Tilly, this issue). In the past several years, many districts and states have moved to alternative approaches to identifying students with disabilities, and include the problem-solving process as a critical component of reform efforts (Ysseldyke & Marston, 1998). When considering best practices in the assessment of written expression, the evaluation questions embedded in the problem-solving approach should guide school psychologists' recommendations for appropriate sources of data for decision making.

Assessing Writing Within a Problem-Solving System

As depicted in Table 1, evaluating written expression requires a clear understanding of the question being asked. Within a problem-solving system, the breadth of assessment extends beyond examining discrepancies within the child (Tilly, Reschly, & Grimes, 1998; Ysseldyke & Marston, 1998) to contributing factors such as curriculum, instruction, and environmental variables (Heartland Education Agency 11, 1996). Educational decision making changes from simply verifying that a problem exists (i.e., Problem Verification) to solving problems once they have been identified (i.e., Problem Solution).

Problem solving prior to an initial evaluation requires the development of an intervention plan that has a legitimate chance of being successful. To best ensure this, a problem-solving team should be assembled that collects and analyzes information according to the student's strengths, the problematic areas in writing, possible influencing factors, and plausible interventions. A plan should be developed for monitoring the student's response to the intervention. If the student does not respond well to the intervention, then the team may move closer toward determining that the student has a disability. In this case, it is likely a referral would be made for a more formal evalua-

858

Table 1. Evaluation questions during problem solving, prior to and during an initial evaluation

Educational decision being made: problem-solving efforts prior to an initial evaluation

General problem solving questions

- What are the functional strengths of the child, family, and school?
- What are the specific areas of concern in writing?
- What are contributing causes of the concern related to curriculum, instruction, environment, and the learner?
- What do we think is the most likely contributing cause, and what can be done to make things better?
- What interventions have a high probability of success and are manageable to implement?
- What supports are necessary to implement the recommendations?
- What are our expected goals for the student, and how will we know if the intervention is working?

Educational decision being made: entitlement determination

Entitlement Component 1: Evidence of resistance to reasonable general education intervention efforts.

Evaluation questions

- What appears to be effective or not effective with this student?
- What do the data tell us about where to go next?

Entitlement Component 2: Evidence of a severe discrepancy from peers' performance levels in the area(s) of concern.

Evaluation questions

- What is the magnitude of the presenting problem?
- Is the discrepancy evident across both sources and agents of information?

Entitlement Component 3: A data-based description of the resources necessary to improve and maintain the individual's rate of learning at an acceptable level.

Evaluation questions

- Given the presenting concern and response to past interventions, what needs to be done to enable the child to participate and progress in the general education curriculum?

Entitlement Component 4: Convergent evidence logically and empirically supporting the teams' decisions.

Evaluation questions

- Is this a student with a disability as defined by IDEA or § 504?
- Does this student need specially designed instruction to benefit from his/her education?

Educational decision being made: instructional planning

Additional questions

- What are the measurable annual goals for this student?
- What interventions will be initiated to enable the student to make adequate progress in writing?

tion, but the eligibility team would continue to use the problem-solving approach to make an entitlement decision.

Making formal decisions about problems in written expression requires an investigation of instruction, curriculum, environment, and learner variables that may be central to the problem (see Table 2). Assessment techniques such as record review, interviews, observations, and tests are useful in understanding those factors. With the current emphasis on the general education curriculum and functional assessments in the 1997 Individuals with Disabilities Education Act (IDEA), school psychologists are increasingly expected to access and use a variety of data sources in making decisions about students and programs.

REVIEW

Assessing written expression lends itself to record review. It is important to understand grade-level expectations within and across subject areas, and what the student's current performance is in relation to past performance. School psychologists should summarize expectations and the prerequisite skills necessary for student success. For example, Table 3 depicts a series of grade-level outcomes, which a school psychologist could use to summarize the skills of a second-grade student under three writing conditions. The first column would indicate the presence or absence of each skill when the student was dictated sentences. In the second column, these same skills would be assessed when the student wrote in response to a story starter, and in the third condition those

Table 2. Data sources to assist with problem-solving efforts

Domains	*Review*	*Interview*	*Observation*	*Test*
Instruction	• Writing requirements for class work in writing and across subjects • Feedback provided to student on class work	• Allocated time for writing (teacher-led and independent time) • Expectations of writing within and across subjects • Preferred instructional practices • Methods used to monitor progress	• Amount of instructional time in writing • Effective teaching practices (pacing, questioning, check for student understanding, motivational strategies, relevant practice, feedback) • Classroom routines and management	
Curriculum	• Grade-level outcomes • Scope and sequence of skills taught • Prerequisite skills required to complete work • Scaffolding options provided within curriculum • Amount of review afforded for each skill	• Continuity of curriculum across grade levels • Expectations of student performance on outcomes • Adequacy of materials to meet diverse learning needs	• Alignment of curriculum materials with instructional expectations	
Environment	• Appropriateness of seating for viewing instruction and for proper handwriting	• Classroom rules and routines known to student • Availability of needed materials for writing	• Student posture and pencil grip while writing • Availability of materials used during writing instruction	
Learner	• Permanent products within current grade and past grades • School records of writing performance (building/district/state tests, classroom grades, anecdotal teacher comments)	• Self-efficacy in writing • Identification of elements covered during instruction • Learning strengths in writing • Degree of understanding of writing assignments and teacher expectations • Student accountability for learning	• Academic engaged time during instruction and independent work • Student response to instructional approaches • Student learning strengths or preferences	• Present levels of performance on measures of writing (e.g., norm- and criterion-referenced tests, classroom assessments) • Rate of learning

Table 3. Example of a written expression assessment summary using grade-level outcomes

Outcome	*Dictation*	*CBM story starter*	*Class assignment*
Conventions			
Capitalization			
Names of days of week and months of year			
First letter in each line of traditional poetry			
Punctuation			
Comma to separate date and year			
Written conversation by quotation marks			
Formation			
Appropriate spacing for punctuation marks			
Appropriate spacing between words			
Prints legibly and neatly			
Maintains margins on all sides			
Writes all lower-case and capital cursive letters.			
Sentence fluency			
Uses appropriate singular or plural noun in sentence			
Writes a variety of types of paragraphs			
Word choice			
Uses pronouns as subjects			
Idea development			
Organization			
Voice			

skills would be assessed when the student wrote in response to a class assignment. This information would help determine writing strengths, specific areas of concern, and discrepancies from expected outcomes.

INTERVIEW

Using interviews as part of the assessment process has been underutilized in education decision making (Howell & Nolet, 2000). Information from interviews not only provides important data for determining what other information to collect, but interviews also provide important data not available by using the other techniques. For example, in an interview, teachers can provide information necessary to understand how they think about the planning and delivering of instruction in written expression and what their goals are after instruction. Interviewing students after writing instruction provides an opportunity to understand what the students have learned and their attitudes toward writing. An excellent interview format for students, teachers, and parents is included as part of *The Instructional Environment System, II* (Ysseldyke & Christenson, 1996).

OBSERVATION

Observations during writing instruction provide excellent information for problem-solving efforts. Observations provide information about student engagement during teacher-led instruction and independent work time, and helps generate hypotheses as to instructional and environmental factors that may be affecting learning. Methods for conducting systematic classroom observations are covered elsewhere (Hintze, this issue). Observations should be scheduled when the teacher provides explicit instruction in the writing process or how to write according to different writing genres (Gersten & Baker, 2001). This helps develop interventions that target specific aspects of teacher-led instruction. It can also help if observations are conducted following teacher interviews and immediately before student interviews, so school psychologists know what to look for and then have specific classroom content they can discuss with the student.

TESTS

Assessments of written expression have received less attention than assessments of other academic areas such as reading and math. Because there are few technically sound measures of written expression available (see Bradley-Johnson & Lesiak, 1989, for review), best practices in the assessment of written expression involves collecting multiple measures of student performance (e.g., support from direct and indirect measures) and looking for patterns of convergence among the measures. This is particularly important when making special education entitlement decisions. Many of the procedures we present are best used for identifying student strengths and weaknesses in order to plan instructional programs and monitor student progress.

Depending on the reason for data collection, student writing samples can be collected by using standardized (e.g., curriculum-based measures, published norm-referenced tests) or non-standardized procedures (e.g., portfolio samples, writing projects). When a student's writing is to be compared with the writing of grade-level peers, standardized procedures should be used. An advantage in assessing writing is that the samples can be used in making many types of decisions (decisions about individual students' progress versus decisions about writing performance when compared with peers).

Six measurable components of written expression distinguish skilled from unskilled writers and provide an organizer for a comprehensive assessment of student writing skills. These six components are (a) fluency, (b) grammar, (c) conventions, (d) content, (e) penmanship, and (f) student knowledge of the writing process (Graham, 1982; Isaacson, 1995). Students may have difficulty in one or more of these areas, and assessment procedures should reflect the classroom teacher's concerns regarding student writing problems as well as actual student performance on writing tasks. Techniques for assessing each component are presented with a brief description of the scoring procedure and its primary application in decision making.

Writing Fluency

Fluent writing is the ability to generate words, simple sentences, and compositions of gradually increasing length. Overall, the compositions of students with high incidence disabilities contain fewer words and shorter sentences than the compositions of students in general education (Deno, Mirkin, & Marston, 1980; Myklebust, 1973; Nodine, Barenbaum, & Newcomer, 1985). Fluency can be assessed by determining the number of words written in a specified time period using Curriculum-Based Measurement (CBM) procedures (see Good & Jefferson, 1998, for a summary of technical adequacy evidence; Shinn, 1989) or by summarizing the average length of the sentences written (Cartwright, 1969).

GRAMMAR

Poor grammar is the most frequent complaint teachers have about students' writing (Larsen, 1987). Appropriate grammar includes the correct use of words and combinations of words within sentences. Grammar can be assessed by examining vocabulary and sentence structure.

VOCABULARY

Appropriate and varied vocabulary is essential to good writing. Research suggests that students with high incidence disabilities use less "rich" vocabulary when they write than students without disabilities (Deno et al., 1980; Morris & Crump, 1982). Two convenient ways to assess vocabulary used in a writing sample are determining the *variety* and *maturity* of words used.

A type/token ratio can be used to examine the variety of words used in a writing sample. A higher ratio indicates that the student is using a variety of words, with few words used repeatedly. The ratio is calculated by dividing the number of different words by the total number of words. If the student's ratio is compared with other students, or to previous samples of their own writing, then Cartwright (1969) recommends using the first 50 or 100 words from each writing sample. A qualitative approach to assessing variety is to provide a holistic judgment of the student's choice of words. Skilled writers use a variety of words that convey the intended message in a precise, interesting, and natural way (for more information see Northwest Regional Educational Laboratories website at http://www.nwrel.org).

Use of mature words typically refers to words that contain seven or more letters (Howell et al., 1993). The proportion of large words is calculated by dividing the number of words containing seven or more letters by the total number of words.

SENTENCE STRUCTURE

Sentence structure can be assessed by summarizing the types of sentences students produce, including sentences that are incomplete, simple, compound, complex, run-on, and fragmented (Cartwright, 1969; Howell et al., 1993). Summarizing the types of sentences contained in a writing sample, in terms of percentages, allows for comparisons across samples of varying length. As writers mature, they increase the percentage of compound and complex sentences, and decrease the number of simple, run-on, and fragmented sentences. Bradley-Johnson and Lesiak (1989) recommend assessing the way students structure their paragraphs by attending to (a) the use of topical sentences, (b) the relation between sentences and topic, (c) the logical order of sentences within a paragraph and paragraphs within an essay, and (d) the effectiveness of transition sentences.

Conventions

Writing according to established conventions is difficult for many students with high incidence disabilities, especially in the areas of spelling, capitalization, and punctuation (MacArthur & Graham, 1987; Thomas, Englert, & Gregg, 1987). Differences between students with disabilities and their general education peers occur in words spelled correctly, and simple punctuation conventions (Deno, Martson, & Mirkin, 1982; Tindal & Parker, 1991). Mechanical errors (e.g., punctuation and capitalization) also interfere with the quality and quantity of student writing (MacArthur & Graham, 1987) and strongly influence the holistic judgments teachers make about the sample (Moran, 1982). Techniques to assess the adequacy of writing conventions include determining the (a) number of words spelled correctly, (b) proportion of errors by category, and (c) number of correct writing sequences.

WORDS SPELLED CORRECTLY

CBM procedures use the number of words spelled correctly as an index of student writing proficiency (Marston, 1989). Assessing the number and percentage of words students spell correctly in a given sample can help school psychologists understand the nature of writing problems, the severity of the discrepancy between a student and peers, the focus of interventions, and ways to monitor student progress.

PROPORTION OF ERRORS PER CATEGORY

When writing samples contain excessive mechanical errors, Howell and Nolet's (2000) summary form of 50 capitalization and punctuation conventions can be a useful way to structure interventions. Errors are tallied and transformed into a percentage of errors per 100 words. Categorizing student errors is useful in specifying specific writing concerns and designing and evaluating specific interventions.

CORRECT WRITING SEQUENCE

Determining the number of correct writing sequences is a CBM procedure that provides a quantitative index of writing that considers grammar, fluency, and conventions (Videen, Deno, & Marston, 1982). A Correct Writing Sequence is earned for each pair of adjacent words or punctuation marks that fits the context of the overall sentence. This index assists in determining specific concerns and understanding the severity of concerns during entitlement decisions. This measure is also the most technically sound of the CBM for monitoring student progress (Hubbard, 1986).

Content

Over the past 15 years there has been a sharp increase in the emphasis placed on improving the quality of student writing content. Students with high incidence disabilities tend to experience particular difficulty (a) generating original, and relevant, responses; (b) including the basic elements of a minimal story (Nodine et al., 1985); (c) writing on topic and including basic elements of appropriate text structure (Englert & Thomas, 1987); and (d) organizing text (Englert, Raphael, Fear, & Anderson, 1988; Graham & Harris, 1997). Quality of writing content can be assessed by using an analytic rating scale or ascertaining the degree to which specific text structure components are present in a given sample.

ANALYTIC RATING

Several analytic rating scales are available for assessing the content of student writing. Common across these scales is that they provide an index of writing content by comparing a student's writing to other writing samples that have been rated according to a particular content dimension. For example, the dimensions included in a scale by Tindal and Hasbrouck (1991) are story-idea, organization-cohesion, and conventions-mechanics. Each dimension is rated on a five-point scale, with precise definitions for each point provided to judge the writing samples. Information from analytic rating scales may be particularly useful for supplementing screening decisions and planning instructional programs.

TEXT STRUCTURE COMPONENTS

The degree to which students' writing adheres to specific text structure styles and conventions should be evaluated. The amount of alignment to different text structures depends on the classroom focus and content. From teacher interviews and other sources, checklists of critical elements can be developed and used to check student-writing samples. This technique is most appropriate for planning instructional programs and evaluating progress toward short-term objectives.

Penmanship

Legible handwriting is important in effective writing. In the early grades a great deal of classroom writing instruction may be on focused on legibility (Graham, 1982). Student writing can be evaluated to determine if it contains appropriate (a) spacing between letters and words, (b) letter size, (c) alignment (i.e., proportion of parts of letters in relation to the top, middle, and bottom line), (d) line quality (i.e., pressure consistency), (e) letter slant, (f) letter formation (i.e., correctly formed upper and lower case letters and discrimination when and when not to capitalize), and (g) style (i.e., cursive versus manuscript) (Howell & Nolet, 2000). Assessment results are most useful for determining specific writing concerns and for developing interventions.

Student Knowledge of the Writing Process

Because instructional approaches that stress the writing process are increasingly emphasized in general education classrooms, comprehensive writing assessments should determine student understanding of the writing process, plus critical steps and procedures. To determine if students can apply this knowledge, school psychologists should have students edit a sample of their own writing and discuss additional ways they could improve it. Other important configurations unique to individual classrooms should also be considered for assessment. For example, if the teacher has established a system where peers edit each other's writing, then a target student might be asked to describe how he or she would edit a peer's story. Information gathered from these approaches can be used primarily for planning interventions and summarizing student progress.

SUMMARY

The nature of research on effective writing instruction has changed dramatically over the last 15 years, but effective research practices have yet to be implemented on a large scale in general and special education classrooms. In assessing students' written expression, school psychologists' decision making should be guided by what effective writing environments should look like for students having difficulties learning to write effectively. Good writing instruction is characterized by explicitly teaching students the stages of the writing process. This includes teaching students how to plan what they are going to write, how to translate those plans into a coherent writing sample that follows established writing conventions, and how to improve their first drafts to make them more interesting and polished.

Students also should be explicitly taught how to write according to specific text structure styles. Writing a narrative story is very different from writing a persuasive essay. School psychologists need to know what genres students are expected to write in proficiently and what specific instructional strategies teachers are using to teach students those genres. Finally, students need lots of ongoing and specific feedback on their efforts to become better writers. Establishing a writing environment where students can present their ideas and attempts at writing, and get specific feedback, is essential in helping demystify the difficult and frequently solitary act of composition. Effective feedback can be provided by either the teacher or peers—the main ingredient is that effective feedback includes concrete strategies for improvement.

The actual assessment of written expression involves the systematic collection of data to facilitate decision making. We have suggested that a problem-solving model should be used to contextualize and guide this process. Data sources include both environmental variables and student performance variables. Structured teacher interviews and classroom observations are two primary methods of gathering data on environmental variables. Direct measures of student writing proficiency can be used to screen students for serious writing problems that may require special education to plan instructional programs, monitor student progress, and evaluate the effectiveness of writing interventions. Many methods are available to analyze direct measures of student writing performance. The specific method or methods chosen should reflect the purpose of the assessment, classroom expectations for writing performance, and evidence of student writing problems.

ANNOTATED BIBLIOGRAPHY

Berninger, V. W., & Hooper, S. R. (Eds.). (1993). Preventing and remediating writing disabilities: Interdisciplinary frameworks for assessment, consultation, and intervention [Mini-series]. *School Psychology Review, 22*(4).

This mini-series addresses issues related to the assessment of, and interventions for, writing problems from multiple perspectives. A strong focus is placed on preventing writing problems and the use of assessment and remediation techniques that stem from a theory-driven model of writing development. Articles include a discussion of the relation between oral and written language, evidence of writing problems among middle-school students, and a multi-level diagnostic procedure to assess writing performance. In addition, two articles on interventions address the use of student self-regulated procedures to monitor writing performance and the use of word processors and integrated instructional strategies to increase student proficiency.

Bradley-Johnson, S., & Lesiak, J. L. (1989). *Problems in written expression: Assessment and remediation.* New York: Guilford.

This book examines a variety of approaches for the evaluation and remediation of writing problems. Chapter topics include (a) handwriting, (b) capitalization and punctuation, (c) spelling, (d) vocabulary and word usage, (e) sentence and paragraph structure, (f) production and quality, and (g) remediation of writing problems. While the book does not include the most up-to-date information on remediating written language problems, the authors provide useful checklists, interview formats, and considerations for assessing student-writing samples. A review of 13 norm-referenced tests and 6 criterion-referenced tests is provided in the appendix.

Englert, C., & Mariage, T. (1992). Shared understandings: Structuring the writing experience through dialogue. In D. Carnine & E. Kameenui (Eds.), *Higher order thinking* (pp. 107-137). Austin, TX: PRO-ED.

This chapter provides a good description of environmental components that are likely to lead to student success in developing writing skills. Numerous intervention ideas are imbedded throughout the chapter, related primarily to the writing process and making the components of different text structures explicit. Particular attention is paid to strategies that can be used with difficult-to-teach students and how teachers can improve the writing atmosphere in their classrooms to make writing more enjoyable and beneficial for all students.

Gersten, R., & Baker, S. (2001). Teaching expressive writing to students with learning disabilities: A meta-analysis. *The Elementary School Journal, 101*, 251–272.

This meta-analysis synthesizes research on writing interventions for students with learning disabilities and draws implications for practice. Thirteen studies implementing interventions to improve expository or narrative text were analyzed, and consistently produced strong effects in the quality of students' writing, as well as in students' sense of efficacy and understanding of the writing process. Findings suggest that three components should be part of any comprehensive instructional program. Explicit teaching of (a) the steps of the writing process and (b) the critical dimensions of different writing genres should be provided, as well as (c) structures for providing extensive feedback to students on the quality of their writing from either teachers or peers.

Howell, K. W., Fox, S. L., & Morehead, M. K. (1993). *Curriculum-based evaluation: Teaching and decision making* (2nd ed.). Pacific Grove, CA: Brooks/Cole.

The authors of this book discuss assessing student performance based on a functional teaching-oriented evaluation. Of particular interest are the chapters related to language, written expression, and written mechanics. Flowcharts are provided for each chapter to guide data collection and decision making. Each flowchart includes procedures, decisions, and teaching recommendations. This book is highly recommended for school psychologists and teachers.

56 Best Practices in Curriculum-Based Assessment

Todd A. Gravois
University of Maryland
Edward E. Gickling
Instructional Assessment Consultant
Centreville, Virginia

OVERVIEW

The relationship between quality assessment and quality instruction is the focus of this chapter. For many school psychologists the use of assessment practices to directly influence instructional design and the effective delivery of instruction remains a small part of the school psychologist's overall role. Formal assessment procedures conducted to determine the special education eligibility of students continue to dominate the majority of school psychologists' time (Curtis, Hunley, Walker, & Baker, 1999). The ability of school psychologists to provide relevant and "usable" data for the purpose of designing instruction represents a major challenge. However, it remains a challenge worth pursuing.

This challenge requires school psychologists and other service providers to increase their understanding of the characteristics of effective assessment that directly improves instruction and student performance. A critical component deserving more attention is the role assessment plays in providing data that can produce optimal learning and teaching conditions; that is, data that should be used for planning and delivering the type of effective instruction that leads to maximum student improvement.

The argument for adopting assessment practices that are directed at improving instruction is strongly supported by The National Center on English Learning and Achievement at the University of Albany, SUNY. Researchers studying the performance of first-grade students in classrooms whose teachers were identified as "effective" and "typical" found that "the most striking difference between student performance among the two groups of teachers was that the lowest achieving students in the most effective teachers' classrooms outscored their peers in the more typical classrooms to a significant degree" (National Research Center on English Learning and Achievement, 1998, p. 6). These findings fundamentally challenge the traditional view of using assessment practices simply to find deficiencies in students or to formulate comparisons among students. Instead, the needed focus of assessment should be toward assisting educators in designing and delivering effective instruction (Shepard, 2000).

Instruction is a complex variable that has a substantial influence on student learning (Bloom, 1976). As Ysseldyke and Elliott (1999) indicated, effective instruction is composed of four major components: planning, managing, delivering, and evaluating. Further, each component is supported by a set of empirical principles. While most schools and educators focus on assessment that provides information as to students' progress (i.e., evaluating instruction), there is a critical need for school psychologists to become skilled in assessment practices that support the first component (planning of instruction). A major aspect

871

of planning of instruction is the decision of what to teach and how to teach it. Curriculum-based assessment (CBA) is an assessment process that supports the planning of instruction, especially in gathering useful data for determining what to teach and how to teach it. This chapter provides a context for the use of CBA by describing its basic underlying assumptions and research base. The steps for conducting a reading assessment are also described. Finally, a case study example is presented to illustrate the use of CBA.

CBA DEFINED

The model of CBA discussed here is based on the original work of Gickling and colleagues (Gickling & Havertape,1981). The use of CBA determines "the instructional needs of a student based upon the on-going performance within the existing course content in order to deliver instruction as effectively and efficiently as possible" (Gickling, Shane, & Croskery, 1989, pp. 344–345). The focus of CBA is the development of effective instructional practices that specifically connect the prior knowledge and skills of the student to the student's ability to accept new learning. While assessment practices have been traditionally used for classification, placement, and progress monitoring (see, e.g., Kamphaus, Reynolds, & Imperator-McCammon, 1999; Salvia & Ysseldyke, 1985), it is a fourth perspective, that of instructional decision making, that is the primary focus of CBA.

CBA serves two purposes within instructional decision making: (a) to create optimal learning conditions for teaching and learning and (b) to provide corrective feedback during the teaching/learning process. A primary assumption underlying CBA is that learning difficulties result from a mismatch of instruction, curriculum tasks, and the entry skills of the student (Rosenfield & Gravois, 1996). As such, the goal is to assess the student's entry skills in order to design instruction and learning tasks that move the student forward relative to his or her performance in the assigned curriculum.

These purposes and assumptions differentiate CBA from other curriculum-based techniques (Shapiro & Elliott, 1999). In particular, confusion seems to exist in school psychology between CBA and Curriculum-Based Measurement (CBM) techniques (Burns, MacQuarrie, & Campbell, 1999). This confusion, as suggested by Burns and his colleagues, may result from the fact that the two techniques differ fundamentally in their intended purpose and outcomes, but more subtly in their practical implementation. That is to say, while CBA and CBM may require students to read from curriculum material, the two processes yield data used for two very different purposes.

The use of CBM has focused primarily on measuring student's performance for determining the effectiveness of interventions or for formulating comparisons between students (Burns et. al., 1999; Tucker, 1987). CBA, on the other hand, was developed to provide assessment data that allow for the creation of optimum teaching and learning conditions in order to maximize student learning (Gickling & Havertape, 1981). Its ongoing and integrated nature within the instructional process allows for the maintenance of instructional levels and for providing immediate corrective feedback in the monitoring of student progress toward achieving specific instructional goals.

BASIC CONSIDERATIONS

CBA involves inquiring into the learning context in which the student is expected to function. This inquiry specifically seeks to answer the following five questions (Gickling, 1998):

1. What does the student know?

2. What can the student do?

3. How does the student think?

4. How does the student approach tasks that he or she is unsure of?

5. Now, what does the teacher do?

Each question is linked to a particular body of educational research that permits the CBA process to continually integrate an understanding of a student's existing skills and knowledge with the purpose of developing effective instruction. Literature relevant to CBA includes (a) the influence of prior knowledge on learning (Dochy, 1992; Wolfe & Brandt, 1998), (b) providing appropriate levels of challenge (Thomas,

872

1992; Vygotsky, 1999), and (c) ensuring an instructional match (Betts, 1946; Clay, 1993). A key goal for school psychologists interested in becoming proficient in CBA is to understand the link between this literature and the assessment process.

The Importance of Prior Knowledge in the Assessment Process

Prior knowledge is central to all learning. It refers to the skills and experience that a student possesses and reflects the content skills and mental schemas that a student uses to connect new learning to existing knowledge. Wolfe and Brandt (1998) describe the brain's natural tendency to seek connections between new and known information. They suggest that when students cannot connect new information with what they already know, attention disengages and quickly fades away.

Wolfe and Brandt's (1998) discussion of prior knowledge is consistent with Bloom's (1976) concept that success in current learning is highly contingent upon a student's cumulative knowledge and experiences. These concepts are supported within the research literature as well. Dochy, Segers, and Buehl (1999) found that more than 90% of the 180 articles, books, and manuscripts they reviewed reported positive effects of prior knowledge on student performance. Their review also found that between 30 and 60% of learning variance could be explained by a student's entry skills and knowledge.

While activating prior knowledge is increasingly recognized as an important part of effective instruction, the importance of it as part of the ongoing assessment process is frequently ignored and often violated. In contrast to traditional assessment practices that demand the same performance from all students regardless of prior skills or knowledge, the correct use of CBA consciously attempts to honor and incorporate a student's prior knowledge into the assessment process.

Maintaining Appropriate Levels of Challenge

The second area for consideration is the level of challenge presented during the assessment process and the impact of various levels of challenge on students' performance. The importance of appropriate challenge is highlighted within the International Reading Association and the National Council of Teachers of English Joint Task Force's *Standards for the Assessment of Reading and Writing* (1994), which states:

> The quality of information is suspect when tasks are too difficult or too easy, when students do not understand the tasks or cannot follow the directions, or when they are too anxious to be able to do their best or even their typical work. In these situations students cannot produce their best efforts or demonstrate what they know. Requiring students to spend their time and effort on assessment tasks that do not yield high-quality, useful information results in [a] student's losing valuable learning time. Such a loss does not serve their interests and is thus an invalid practice (p. 14).

These standards, consistent with the work of Vygotsky (1999), are supported by other researchers (e.g., Tomlinson & Kalbfleisch, 1998) who have shown that students perform optimally when provided appropriate levels of challenge. The goal for school psychologists conducting CBA is to assess a student's prior knowledge and to use the resulting information to strategically manage the assessment demands at an appropriate level of challenge, one that is neither too high nor too low. To accomplish this function, there is a need for a clear concept of instructional level and a basic understanding of how information processing can adversely affect the performance of a student when the assessment is not conducted on the student's instructional level.

INSTRUCTIONAL LEVEL

Betts (1946) first introduced the concept of instructional level as related to reading performance. He noted that reading comprehension began to falter when the number of unknown words exceeded 5%. This loss of comprehension reflected a challenge level that did not promote student learning, a level he identified as frustration. He also noted when the percentage of known material remained exceptionally high (98% or better), students had no difficulty reading, a level he identified as independent. Between the independent and frustration level was the concept of instructional level—or the level where the maximum amount of teaching and learning progress could be expected.

Research originating during the teacher effectiveness period of the 1970s and early 1980s extended this concept of instructional level. This research demonstrated that teachers who managed the amount of challenge successfully during rehearsal and practice activities at a ratio of 80% known to 20% unknown were consistently able to elevate their students' performance and retention (Archer et al., 1987; Shapiro & Elliott, 1999). Table 1 provides a summary of these ratios for comprehension and rehearsal and practice tasks.

It is important to differentiate the concept of "instructional level" from "grade level," which often accompanies reading materials. In practical terms, instructional level is best understood as the relationship between the student's entry skills and knowledge and the demand of the particular reading passage or page at hand. In this sense, an appropriate level of challenge is a comfort zone created when the student has sufficient prior knowledge and skill to successfully interact with the task and still learn new information.

INFORMATION PROCESSING

A second aspect to consider in establishing an appropriate level of challenge is a student's ability to process new information. A key aspect of a student's ability to process information is the student's working memory. "Working memory is what you are paying attention to at any given point. So everything you are mulling over, making a decision about, or are learning, is at first in working memory" (Goleman cited in O'Neil, 1996, p. 8). Working memory has certain features that directly affect a student's ability to effectively and efficiently process information, features that are relevant to the discussion of instructional level. In particular, working memory requires undivided attention, has a limited capacity, and is developmental in nature. While research recognizes that the limits of working memory remain fairly individualistic, the guidelines researched by Pascuel-Leon (1970), and presented in Table 2, represent a good starting point when working with students.

As can be seen in Table 2, the capacity of working memory gradually improves with age. For example, a 3 year old can retain about one new item in working memory at a time and increasing in capacity to about seven new items (plus or minus two) for an individual 15 years old and older (Miller, 1956). However, these ranges do not imply that first graders can learn only three new items per lesson. Instead, these ranges suggest that new information be strate-

Table 1. Levels of challenge for comprehension and practice tasks

Levels of performance	*Comprehension*	*Rehearsal and practice*
Independent	98–100% known	90–100% known
Instructional	93–97% known	70–85% known
Frustrational	Below 93% known	Below 70% known

Table 2. Researched capacity of working memory by chronological age

Chronological age	*Working memory capacity (number of new items)*

9	4
11	5
13	6
15	7

Adapted from Pascuel-Leon (1970).

gically organized and presented in limited sets so as not to overload working memory.

Introducing information beyond the range of a student's working memory impacts negatively on the student's ability to retain and use new information. When overloaded, working memory loses its efficiency and generally results in fragmented learning. When not actively in use, working memory also clears itself automatically, which is why concerted steps need to be taken to keep new information in working memory (Miller, 1956; O'Neil, 1996).

The percentage values described earlier for instructional levels must be considered in relation to a student's working memory capacity if an appropriate level of challenge is to be created. For example, an instructional level in reading of 95% known words represents an appropriate level of challenge as long as the actual number of unknown words does not violate a student's working memory. That is, 95% of a 100-word passage represents 5 unknown words. This can be considered an appropriate level of challenge for an 11 year old whose working memory capacity is about five new items, but may in fact remain an inappropriate level of challenge for a 7 year old with a working memory capacity of three new items. This knowledge of the research on working memory and on instructional levels gives the school psychologist the information needed to effectively create, manage, and refine an appropriate level of challenge for students being assessed.

Ensuring an Instructional Match

The instructional match is a central concept to CBA and represents a culmination of the research on prior knowledge and on appropriate levels of challenge. As Spady (1984) noted, "excellence occurs when the instructional system is able to provide the learner with an appropriate level of challenge and a realistic opportunity for success on a frequent and continuous basis." This concept of instructional match applied to CBA requires the level of challenge (task demand) to be constantly balanced against the student's entry skills (prior knowledge and working memory capacity) for the student to demonstrate his or her best efforts.

In this sense an instructional match represents the interplay between a student's existing prior knowledge, the student's capacity for information processing, and the demands presented by the learning task. An appropriate match lets the student integrate reasonable amounts of new information successfully into existing knowledge. This type of match represents an "appropriate fit" or point where the student can comfortably engage in the assessment or learning task without being excessively challenged and frustrated. It is also the point where the assessor can truly determine what the student knows, what the student can do, how the student thinks, how the student approaches new learning tasks, and where to begin focusing instruction.

BEST PRACTICES IN CBA IN READING

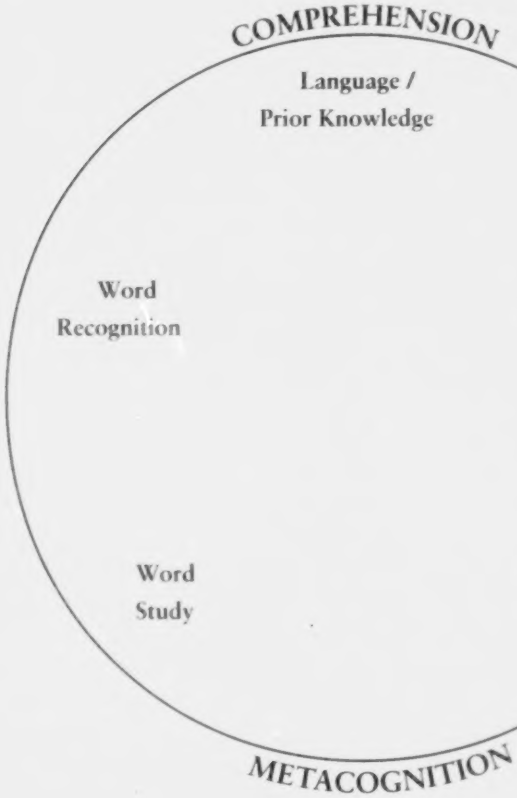
Meaningful assessments must integrate knowledge of the critical dimensions of reading with sound research practices supporting the concept of instructional match if assessments are to be useful tools in helping children become better readers. The following section introduces seven essential dimensions of reading and illustrates how these dimensions are used to guide the assessment and instructional process.

Dimensions of Reading

CBA has embraced a core of professional practices that maintains a balanced perspective to reading and the reading process. This perspective acknowledges students' reading performance as being a process of orchestrating skills and knowledge to derive meaning from the printed text. The research identifies broad key dimensions of reading that include phonemic awareness, the alphabetic principle, the development of speed and automaticity in word and text reading, and the development of comprehension strategies (Lyon cited in Mathes & Torgesen, 2000) that are interwoven and interdependent (see also Figure 1). It is recognized that both good and poor readers manage and interact with printed material by addressing these dimensions in different ways. It is the responsibility of the school psychologists conducting CBA to manage the assessment tasks and process in an effort to determine how each student orchestrates his or her reading skills within and across these different dimensions.

Comprehension and metacognitive strategies represent defining and overarching dimensions of reading. Both contribute to, and directly result from, the

Figure 1. The essential dimensions of reading assessment



effective application of the other five dimensions, displayed in Figure 1, including a student's language and conceptual understanding, word recognition, word study, reading fluency, and responding. For example, knowledge of individual words contributes to a student's overall comprehension of the reading text. Likewise, being able to attack a limited number of unknown words successfully and to read fluently positively influences the student's ability to monitor and to understand what is read.

The school psychologist's actions are directed at exploring a student's skills and knowledge in each of these dimensions. A positive answer to dimension specific questions (see Table 3) is contingent upon the student's being able to function at his or her comfort zone or instructional level during the assessment process itself. Table 3 provides a working definition for each of the seven reading dimensions and a summary of questions to be answered for each dimension as part of the CBA process.

While the school psychologist may not be able to answer every question during an initial assessment, the data collected should provide an effective starting point for working with the student and/or provide direction for additional assessment activities. Our view is that CBA is an ongoing process and other relevant data will constantly be forthcoming.

Steps in the CBA Process in Reading

CBA should be thought of as a process, and not as a singular event, and that it often results in information received in one aspect of the assessment process assisting and directing the assessment process in other aspects. The steps associated with CBA are designed to achieve a specific outcome. That outcome is to

Table 3. Reading dimensions defined and assessment questions

Essential dimensions	*Essential questions*
Language/prior knowledge The grammatical and broad range of experience that gives meaning to the student.	Does the student have adequate language, concepts, and experience to understand the text?
Word recognition The ability to identify, pronounce, and know the meaning of words that are linked together in print.	Does the student possess a sufficient sight-word pool to read and comprehend the selection?
Word study The use of organized approaches for unlocking words outside one's own sight vocabulary.	What strategies does the student use to unlock or figure out unknown words?
Fluency The speed of reading and the use of phrasing and expression during reading.	Can the student read with adequate speed and expression orally? How well does the student read silently?
Responding The ability to reply orally or in writing to what was said or read.	Can the student retell or write about what was read accurately and effectively?
Comprehension The ability to confirm, predict, and reflect on, and retain the author's message.	Does the student grasp the meaning of what the author was conveying?
Metacognition The ability to monitor and to regulate one's own learning.	Does the student use specific strategies for monitoring his or her own learning?

explore the student's orchestration of the seven reading dimensions and to answer the key questions related to what a student knows and can do for the purpose of designing effective instructional conditions for learning. However, to achieve this outcome the assessor must manage the assessment tasks and conditions so that the student is engaged in tasks under instructional level conditions *throughout* the assessment process.

The global steps involved in the CBA process include

Step 1. Selecting of materials

Step 2. Building a relationship

Step 3. Assessing the student while ensuring an instructional match

Step 4. Sampling the student's performance

Step 5. Matching results to needed instruction

Step 6. Teaching the student

These global steps are designed to develop a working relationship with the student and to gain a picture of the student's performance patterns within the constraints of tasks at the student's instructional level. Progress through the steps, though, is not necessarily linear. Instead, the assessor is confronted by decisions that must be made throughout the assessment. The following section provides a description of each step and decision questions raised throughout the reading assessment process.

STEP 1. SELECTING MATERIAL

CBA makes use of classroom and curriculum material (i.e., current reading texts, novels, basal readers, etc.) as the basis for the assessment process. In considering which specific materials to have available, the school psychologist should remain aware that the major dilemma frequently confronting teachers of a poor reader is that the student's language and conceptual skills are often *at or above* grade level while their ability actually to read is *below* expectations. This discrepancy between language and reading skills poses an equal dilemma for the assessor as to what material to use for the CBA.

Since the CBA process is designed to assess *all* of the reading dimensions, including the student's language and conceptual knowledge, the preference is to begin with grade-level reading material (i.e., material expected to be read by grade-level peers) even if the student is reading below the expected grade-level. If the student is currently reading other material, then samples of that material should also be available. Having the student's current reading material, as well as grade-level expected text, permits the assessor to have a sufficient range of material to fully capture a student's knowledge and skills across all dimensions.

STEP 2. BUILDING A RELATIONSHIP

If the school psychologist is unfamiliar with the student, then the school psychologist should take time to establish a working relationship. The school psychologist should visit with the student and put the student at ease and talk about the reason for working together. The reason is not to test the student, but to find out what the student knows and what the school psychologist can do and to help the student become a better reader. Even the reader who struggles most wants to demonstrate what he or she can do and what he or she knows. This initial conversation is also an opportunity to observe the student's language skills and concept development

STEP 3. ASSESSING THE STUDENT WHILE ENSURING AN INSTRUCTIONAL MATCH

Regardless of the stated "grade level" or difficulty of a particular text, there is considerable variability in the readability of most printed texts. Before having the student read within the selected material, the school psychologist assesses the student's current language and word recognition skills using the following two activities. These activities also assist the psychologist in determining whether the material will represent an instructional match permitting the assessment process to continue.

Reading to the Student. Assess the student's listening capacity and concept familiarity with the curriculum being taught in the classroom (i.e., grade-level material) by reading to the student and speaking with the student about what was read. After reading to the student, the student is encouraged to "talk about what was read" or "talk about what had happened so far in the material." At this point in the assessment, the assessor is observing the student's prior content knowledge, listening capacity, and oral language capacity to comprehend grade-level material.

Conducting a Word Search. By using a passage with content that appears "workable," the school psychologist begins to assess the student's word recognition skills and sight vocabulary relative to the selected text. While remaining aware of the research on instructional level and information processing, the assessor selectively points to words that the student has a high probability of knowing and points intermittently to words that appear more difficult. For most students this translates to pointing to three to four basic sight words (i.e., "it," "the," "when," "went," etc.) and then pointing to a more difficult word (e.g., a word with multiple syllables, irregular phonetic patterns) and then pointing to easier words again. The school psychologist may also engage the student in discussing the meaning of selected words as part of assessing the student's conceptual understanding of key words related to content.

The importance of maintaining high ratios of known to unknown words is the underlying reason for strategically pointing to easier and then harder words as part of the word search. This pattern of pointing to selected words is continued until the school psychologist gains a better idea of the student's working sight vocabulary. The goal is to assess the ratio of known to unknown words and then to decide whether the number of unknown words would represent a frustration level for the student or would violate the working memory capacity expected for the student's age.

The results of these first two activities, reading to the student and the strategic word search, leads to the first decision question: *Does the student possess the language and conceptual background and the word-recognition skills to comprehend the selection?* If the answer is yes, then the reading assessment can continue within the current passage. If the answer is no, then the school psychologist must take additional steps to ensure an instructional match before continuing with the assessment.

While the most common option chosen by assessors for gaining an instructional match is finding lower grade-level material, CBA offers additional options. For example, if the student's background knowledge of the content or the student's sight vocabulary is only slightly limited, then the school psychologist could strategically teach the student the concepts of a few sight words needed to elevate the passage to an instructional level. The school psychologist could also review the previous or following pages to select another passage within the same work, that would meet the student's language and vocabulary needs. Still another option is to only use segments of the passage that contain vocabulary matched to the student's skill. Finally, the school psychologist could create material that would be within the student's instructional level based upon the results of the word search. That is, the school psychologist could utilize the results of the word search to create a passage related to the existing content but composed of an appropriate ratio of known and unknown words. Such assessor-created material would provide the benefit of maintaining an instructional level and also provide material that remains related to the content of the original text.

The key in all of these options is that the task demands are only relevant when considered in relation to the student's skills. As such, these options allow the school psychologist to strategically manage the tasks and establish an instructional match before continuing with the assessment process.

Sampling Content Reading. The student reads orally from the task derived from the step above. Reading can be done in familiar or unfamiliar content. The school psychologist observes the student's reading and records how the student orchestrates the additional reading dimensions of fluency, word study, and metacognitive strategies. Fluency can be represented by the rate at which the student reads (i.e. correct words per minute) (see, e.g., Deno & Mirkin, 1977; Hasbrouck & Tindal, 1992). But fluency also refers to the rhythm and phrasing used by the student. Word study refers to the strategies the student utilizes to unlock words that the student does not know by sight. The assessor analyzes the student's errors and observes to see if the student uses decoding strategies, context clues, or other means to gain understanding of particular words. Running records (see, e.g., Clay, 1993) can be used to record the student's performance in these areas.

Assessing Comprehension. Unaided questioning techniques followed by aided questioning techniques are used to assess the student's general reading comprehension. The school psychologist begins with general unaided retelling prompts (e.g., tell me about the story, tell me more, etc.) and then proceeds to more aided and directed questioning (e.g., who was in the story, what was the story about, etc.) based upon the student's responses.

The student's performance during sampled reading raises a second set of decision questions on the part of the assessor: *When reading material at an instructional level, what word-study and reading fluency patterns did the student display? How well did the student understand what he or she was reading and how much assistance was required by the student to demonstrate comprehension?*

STEP 4. MATCHING INSTRUCTION

On the basis of the CBA process conducted, the school psychologist can now address the next decision question: *What specific reading dimensions require immediate support?* The specificity of the assessment process, and the fact that the use of instructional level material helped facilitate the student's optimal performance, creates a clearer understanding of possible reading difficulties and, more important, the type of instructional strategies that can be used to support reading improvement. Our experience has consistently found that the specificity derived from the assessment process results in greater ease in matching instructional activities to the student's assessed needs.

STEP 5. TEACHING THE STUDENT

The logical conclusion to the assessment process is to implement specific reading strategies to address the assessed areas of need—while maintaining a balanced perspective with regard to the reading dimensions. The overriding goal of the assessment process, that of keeping all activities within the student's margin of challenge, now evolves into the overriding goal of the teaching process. The teacher targets the areas of need and continuously develops word identification, fluency, and comprehension skills concurrently while working with material at an appropriate instructional match. The teacher's responsibility is to review frequently, to monitor, and to record progress to ensure continued growth of the student's reading skills. This represents the final decision question faced by the assessor: *What fine tuning needs to occur to ensure ongoing reading success?*

Case Study: Cameron

A third-grade teacher identified four students who were having trouble reading. She initially thought their problems related to difficulties with letter-sound correspondence, the blending of letters, and poor word recognition. The parents of one boy, Cameron, had asked for special education testing, thinking that he might have a learning disability. The teacher did not feel her concerns for Cameron represented a suspected learning disability, and asked if CBA could be conducted and the data used to assist in making an instructional decision and addressing the parent's request.

STEP 1. SELECTING MATERIAL

Cameron brought the material his teacher was using for reading instruction to the conference room. The particular selection was a story the class had already read (i.e., familiar text). The selection was entitled "Miss Nelson is Missing!" by Harry Allard and James Marshall (1977).

STEP 2. BUILDING A RELATIONSHIP

Cameron, after becoming acquainted with the assessor, was told the purpose of the session. He was told that his teacher and others knew that he wanted to be a better reader and that all of us wanted to help him become one. He was told that it was also our (the assessor and teacher's) job to make sure he felt comfortable working with us. For now, Cameron was told the goal was to look for what he knew and what he could do. It was stressed that if he came to a word he did not know or to a concept he did not understand, he was not to worry.

STEP 3. ASSESSING THE STUDENT WHILE ENSURING AN INSTRUCTIONAL MATCH

Reading to the Student. Cameron and the assessor reviewed pictures related to the story, and then Cameron was given an opportunity to describe what he saw and what he thought the pictures represented. Cameron was then asked to listen to the following portion of the story:

> The kids in Room 207 were misbehaving again.
> Spitballs stuck to the ceiling.
> Paper planes whizzed through the air.
> They were the worst behaved class in the whole school.
> "Now settle down," said Miss Nelson in a sweet voice.
> But the class would not settle down.
> They whispered and giggled.
> They squirmed and made faces.
> They were even rude during story hour.
> And they always refused to do their lessons.
> "Something will have to be done," said Miss Nelson (pp.3–7).

When asked to retell what was read, Cameron said that the kids were misbehaving and were the worst class in school. He also gave two examples of how the children were misbehaving. When aided with prompts, Cameron could give more examples of the students' misbehavior.

Conducting a Word Search. Since letter-sound correspondence was viewed as an area of difficulty, a brief phonics assessment within the material was conducted. By using a modification of the word search procedure, the assessor pointed to individual letters within the selection and asked Cameron to identify the associated sounds. This portion of the assessment indicated that he knew his initial and final sounds but was having some difficulty with vowel patterns in words.

To gauge Cameron's working sight-word vocabulary, a word search was conducted on the next few lines of text. The underlined words were unknown.

> The next morning Miss Nelson did not come to school.
> "Wow!" yelled the kids. "Now we can really act up!"
> They began to make more spitballs and paper planes.
> "Today let's be just terrible!" they said (p.8).

Results of the word search indicated that Cameron had a good knowledge of sight-words. He possessed a fair number of small structural words (i.e., "the," "did," "not") as well as a number of common words (i.e., "paper," "today," "morning"). The breakdown seemed to occur with two and three syllable words.

The word search also indicated that Cameron's word recognition accuracy was about 88% (4 unknown, 32 known), and the passage would be below an instructional level if he were asked to read. The assessor had several options including using lower-level reading material, using another segment from within the same story, or to strategically teach Cameron in order to elevate the passage to a better instructional match.

The decision was to utilize the current passage and to do strategic teaching prior to having Cameron read. The particular structure of the four unknown words provided an opportunity to teach Cameron some word study strategies that would serve to elevate the passage to an instructional level. The assessor discussed with Cameron the relationship between consonants and vowels and the role of each in breaking bigger words into syllables. Cohen's (1998) "Spot and Dot" technique was used to demonstrate how vowels are used to identify the letter patterns that form syllables. The assessor also discussed common letter patterns, such as *be, ed, an, an,* and *er* in words, and how to look for little words in bigger words such as *it* and *ball* in *spitball.* With limited practice using the strategy with the unknown words, the assessor was ready to sample Cameron's reading within this portion of the text.

Sampling Content Reading. Cameron was instructed to read the passage orally. He was able to read the 34 words correctly (94% accuracy) in 27 seconds (approximately 75 words per minute) when provided material at his instructional level._

Since Cameron remained engaged and motivated to continue reading, the assessor allowed him to read further into the story. While the following passage was noted to be known words at a frustration level (approximately 80%) it did provide additional information regarding Cameron's reading rate and error patterns. The unknown words again were underlined.

> "Not so fast!" hissed an unpleasant voice.
> A woman in an ugly black dress stood before them.
> "I am your new teacher, Miss Viola Swamp."
> And she rapped the desk with her ruler.
> "Where is Miss Nelson?" asked the kids.
> "Never mind that!" snapped Miss Swamp.
> "Open those arithmetic books!"
> Miss Nelson's kids did as they were told (pp.8–10).

In this passage Cameron's oral reading rate without any prior vocabulary development was 36 words per minute (or about one-half the rate noted when he read at instructional level). This measure would be considered an indication of Cameron's unrehearsed or cold reading performance. An analysis of his unknown words again revealed difficulty with multi-syllabic words and, more specifically, difficulty with past tense endings (i.e., *ed*). When Cameron was allowed additional practice with using the "Spot and Dot" strategy with unknown words, followed by a re-reading of the passage, his reading rate increased to 57 words per minute.

Assessing Comprehension. The next step in the process would be to assess Cameron's reading comprehension. However, in this case the assessor chose not to proceed with that part of the assessment. This decision was guided by the results of the assessment process already conducted. First, the material selected was familiar to Cameron and may have been discussed as part of a classroom lesson. As such, it may not be an accurate measure of his reading comprehension. Second, Cameron's listening comprehension, assessed earlier by having him respond to material orally read by the assessor, was not found to be a concern. Finally, the assessor noted that Cameron's difficulty decoding multi-syllabic words could itself negatively affect his reading comprehension.

Since the goal of the assessment is to identify immediate needs in the reading dimensions, and since comprehension is directly related to a student's word recognition and word study skills, the decision was made not to move the assessment into what might be a frustrating experience. Reading comprehension could be assessed at a later point once instruction began in the target areas cited above. The decision by the assessor to postpone the assessment of comprehension represents the fluid and flexible nature of CBA and demonstrates how results from one aspect of the assessment steps guides the assessment process later.

STEP 4. MATCHING INSTRUCTION

Results of the CBA process highlighted three possible areas of immediate need in the reading dimensions: fluency, word study, and use of metacognitive strategies. Cameron's difficulty in decoding multi-syllabic words and words with past-tense endings and the lack of a strategic approach to address unknown words were seen as viable areas to address.

Three specific strategies were considered to support Cameron's progress in these areas. First, Cameron would be taught the "word search" procedure and how to use it himself as a pre-reading strategy. Increasing Cameron's skills at self-identifying words needing practice prior to reading would place him in a more strategic position to be successful. He would also be developing his own metacognitive skills in approaching reading in narrative and ultimately in content material.

Cameron's accurate use of the word search technique would support the second set of instructional strategies, which focused on the direct teaching of letter/vowel patterns by the teacher and the opportunity for additional practice of the "Spot and Dot" technique.The intervention would be to have Cameron pre-read and identify words needing practice using the word search technique. Then the teacher would strategically teach the necessary skills or reinforce particular techniques to decode patterned words.

Finally, the strategy of "chunking" or "phrasing" was to be introduced by the teacher to show Cameron how words are grouped to form discrete units of meaning. The *chunking* strategy directly teaches students to look for small phrases or chunks of words within sentences that describe a thought or convey meaning. Students are then asked to read the phrase or chunks together according to these thoughts. As an example, the underlined phrases within the following sentence would be highlighted and practiced with Cameron.

> A woman in an ugly black dress stood before them.

This strategy could also be linked to the "Spot and Dot" technique in that just as Cameron looked for clusters of letters within words he should also practice looking for clusters of words within sentences.

STEP 5. TEACHING THE STUDENT

The next step was to formulate specific progress goals for Cameron and to teach him the various strategies described above. Central to this process was the teacher's skill in creating and maintaining the opportunity for Cameron to read within a variety of instructional and independent level materials to reinforce the application of the skills being taught.

Cameron's teacher and the assessor set the following short-term goals for Cameron based upon the information derived from the assessment process:

1. When reading unfamiliar material for the first time, Cameron will consistently apply the use of the "Word Search" strategy 90% of the time.

2. When seeing unknown multi-syllabic words for the first time, Cameron will apply the use of syllabication rules (i.e., "Spot and Dot") with 95% accuracy.

3. When given instructional level material, Cameron will read at 80 words per minute.

4. When given independent level material, Cameron will read at 100 words per minute.

The last two goals related to fluency were established by utilizing the data in published research on expected fluency performance for third graders (see, e.g., Hasbrouck & Tindal, 1992). The setting of interim and long-term goals would occur after the interventions were in place and progress was monitored toward achieving the short-term goals.

FOLLOW-UP TO CAMERON

Two weeks after the CBA and after designing appropriate instruction to address the assessed needs, Cameron's teacher indicated that he was doing much better and had improved in his reading ability. After sharing Cameron's progress with his parents, the teacher and parents agreed to defer testing for special education services.

SUMMARY

The CBA process is based on established research principles of learning which aid school psychologists and educational professionals gain an accurate picture of a student's current knowledge and skills. CBA represents best practice because the use of CBA provides an assessment method that results in the implementation of sound instructional strategies that produce positive growth in student performance. Since CBA honors a student's prior knowledge and the student's capacity to interact with new information, the results also provide the necessary information to create optimal teaching and learning conditions within the classroom setting.

While the underlying principles of CBA can be applied to all curriculum content areas, this chapter highlighted its application to the area of reading. By following the basic steps of CBA, the school psychologist is able to select appropriate material, assess the student's performance within instructional level material, and identify the dimensions of reading requiring immediate support. The specificity of the results assists school psychologists, teachers, and other professionals to design, implement, and evaluate instructional strategies targeting these areas.

For school psychologists the use of CBA requires an increased understanding of the role of assessment for instructional decision making. The use of CBA requires that school psychologists be open to incorporating assessment techniques that go beyond determining deficiencies within the individual students or simply comparing performance among students. The successful integration of CBA into the school psychologists' repertoire of skills will also require the development of consultation skills that will allow the CBA process and results to be effectively and collaboratively shared with teachers.

Finally, if school psychologists will make use of CBA as a part of their professional practice and incorporate the principles of prior knowledge, the appropriate levels of challenge, and the concept of instructional match, then CBA will serve them well. They will be in a better position to meet the learning needs of students who struggle academically and to influence the instructional practices of the teachers who work with these students.

57 Best Practices in Providing Accommodations for Assessment

Lynn S. Fuchs
Peabody College of Vanderbilt University

OVERVIEW

The purpose of this chapter is to consider issues pertaining to the participation of students with disabilities as they participate in state and school district testing programs within general education accountability frameworks. This initial overview provides an overview of the context for this movement and identifies one key issue necessary to promote meaningful participation.

Historical Context

In the United States, the practice of assessment in the public schools often mirrors national trends, values, and problems. And ironically, today's most pressing issues, at the turn of the twentieth century, echo themes important at the turn of the last century. For example, the diversity of the nation's school population is increasing again (Hodgkinson, 1995). Currently, 8.7% of Americans are foreign born, the highest percentage since before World War II. In addition, in recent decades, the population has become more diverse ethnically, with Hispanic Americans increasing by 65%, Asian Americans by 32%, African-Americans by 16%, and European-Americans by only 8%. Moreover, the proportion of school children living below the official poverty line is increasing steadily (Stallings, 1995). At the same time, however, commitment to democratic principles remains strong, just as it was in the early part of the twentieth century. This commitment is reflected in the schools' initiatives to de-track classrooms (Braddock et al., 1992), whereby students at all achievement levels within a grade are grouped for instruction, and to include students with disabilities in mainstream classrooms (Fuchs & Fuchs, 1994).

Concurrently, however, the changing economic environment of the 1990s has created demands for a more highly skilled labor pool, which can tackle increasingly complex problems and apply knowledge in flexible ways to solve novel problems. This, in turn, has led to renewed pressures from the business community for educational accountability. Today, accountability is operationalized in terms of how much and what type of knowledge students acquire as a function of schooling (McDonnell, McLaughlin, & Morison, 1997).

How are these forces reflected in the critical assessment issues of our time? Increasing complexity in our workplace has helped shape the direction of the current education reform movement, which seeks to upgrade and enrich the content of our schools' curricula. The goal is for students to learn complex skills, such as problem solving, written expression, critical thinking, and social cooperation within authentic contexts (Darling-Hammond, 1992; Mory & Salisbury, 1992).

At the federal level, four major pieces of legislation embody the goals of this standards-based reform (McDonnell et al., 1997). First, in 1994, Goals 2000 was enacted at the behest of the Clinton administration. Goals 2000 codified a set of national education goals for all students and sought to encourage states to adopt content and performance standards. Importantly, Goals 2000 was clear in stating that the term *all students* includes those with disabilities. Goals 2000 also specifically declared that state assessments should provide for the participation of all students with diverse learning needs, along with the adaptations and accommodations necessary to permit participation.

Of course, direct federal influence was limited under Goals 2000. So, the Clinton administration and congressional supporters of standards-based reform attempted to reinforce this policy by making challenging content standards a centerpiece of other federal programs. This strategy is evident in the Improving America's Schools Act, the 1994 reauthorization of the Elementary and Secondary Education Act. This piece of legislation explicitly required that, as a condition for obtaining funds under Title 1, states and local districts submit plans that (a) provide for challenging content and performance standards, (b) state assessments and yearly reports on meeting standards, and (c) provisions for teacher support and learning aligned with new curriculum standards and assessments. And, as with Goals 2000, Title I acknowledges students with disabilities and specifies that they are to be included in the teaching and assessment of state content standards. The legislation also directed all children to participate in annual assessments and that reasonable accommodations and adaptations be provided students with diverse learning needs.

The participation of students with disabilities in standard-based reform was reinforced further with the 1997 amendments to the Individuals with Disabilities Education Act (IDEA 97). IDEA 97 requires states to include all students with disabilities in their accountability programs and to provide students with disabilities the accommodations they need to do so.

How to Promote Meaningful Participation: Valid Accommodations

Prior to the passage of IDEA 97, participation rates of students with disabilities in state assessments were dismal. As recently as 1995–1996, when the first tests of some accommodations occurred, only 45–75% of students with disabilities participated in the National Assessment of Educational Progress, and states' and districts' annual testing programs continued to exclude large numbers of students with disabilities. In addition, even when students with disabilities were permitted to take high-stakes assessments, some states or districts excluded their scores from public reports (Thurlow, Scott, & Ysseldyke, 1995).

Low participation rates, along with questionable reporting practices, were disappointing. If schools are to consider the needs of students with disabilities deliberately and proactively in reform and improvement activities, then the outcomes of these students, who constitute the vast majority of the population of individuals with disabilities, must be represented in public accountability systems. Only with representation in assessment databases will schools be held accountable for the learning of students with disabilities, be encouraged to establish challenging goals for students with disabilities, and be prompted to identify more effective instructional approaches for students with disabilities. Unfortunately, before meaningful valid participation can be accomplished, a critical assessment problem must be addressed: establishing valid accommodation policies.

Accommodations are changes in standardized assessment conditions introduced to level the playing field for students with disabilities by removing the construct-irrelevant variance (or barriers to performance) created by the disability. Valid accommodation policies produce scores for students with disabilities that measure the same attributes as standard assessments measure in non-disabled individuals (McDonnell et al., 1997). On one hand, disallowing fair, valid accommodations prevents students with disabilities from demonstrating their abilities. On the other hand, overly permissive accommodation policies inflate scores and inadvertently reduce pressure on schools to increase expectations and outcomes for students with disabilities.

With the passage of IDEA 97, states were required to develop accommodation policies. As these policies have been developed, it has become clear that tremendous variability in these policies exists (Thurlow et al., 1995; Ysseldyke, Thurlow, McGrew, & Shriner, 1994). In fact, some states prohibit the very accommodations that other states recommend. Moreover, decisions for individual students with disabilities are typically formulated idiosyncratically with vague decision-making rules that often focus on superficial variables. Without well agreed upon criteria for determining whether and if so which accommodations are allowed, comparisons between schools, districts, or states with varying accommodation policies are unfair and meaningless. And, unfortunately, research on the validity of scores from accommodated assessments is limited. Most available data are restricted to college admissions and other postsecondary tests. (See below for a review of this research base.) Clearly, research is needed on procedures to identify fair technically sound and valid accommodations for students with disabilities.

Nevertheless, some of the stickiest questions about the meaningfulness of accommodations occur for students with learning disabilities (LD). This is unfortunate because students with LD constitute the majority of the disabled population. Questions about accommodations are particularly difficult for these students for two reasons. First, this group of learners is especially heterogeneous. It is well known that school-identified LD can be subtyped into clusters with varying underlying problems (Morris et al., 1998). This makes conceptual analysis of meaningful accommodations impossible (as it might be, for example, with students with visual disabilities). Instead, heterogeneity within the population of learners with LD dictates empirical study with a strong focus on individual differences.

The second problem raising important questions for students with LD is the nature of the cognitive problems these students experience. The most distinguishing characteristics of learning disabilities are reading and math deficits (Kavale & Reece, 1992), and most high-stakes assessments, of course, directly measure or rely heavily on those very skills. Therefore, many accommodations popular for students with LD (such as extended time, decoding questions, encoding responses) may distort the meaning and interpretation of the scores. In essence, because the disability is intertwined with the constructs being measured, allowing accommodations may effectively exempt those students with LD from demonstrating the cognitive skills the assessments are designed to index. Fortunately, methods exist to address these problems.

BASIC CONSIDERATIONS

As schools struggle to preserve the meaningfulness of test information, they must identify strategies for assigning accommodations to students and procedures for operationalizing those accommodations. To identify methods for assigning and operationalizing accommodations, a thorough understanding of test theory and measurement principles is necessary. Within school settings, the professional most capable of providing this guidance is the school psychologist. In this section, therefore, we provide an overview of the literature on test accommodations.

Strategies for Studying the Validity of Test Accommodations

Three basic strategies are available for studying the validity of testing accommodations. The first approach relies on the notion of differential effects; that is, an accommodation is valid if it boosts the scores of students with disabilities more than it benefits students without disabilities. This principle is evident in the logic behind the use of a Braille accommodation for students with visual disabilities. One can predict that Braille will make a reading test accessible for students with visual disabilities and thereby boost students' scores over what we might expect with a standard administration. By contrast, for students without disabilities, we would expect a Braille accommodation to depress scores. This illustrates the principle of differential boost. In a similar way, research that employs a differential effects approach demonstrates the validity of accommodations when an accommodation boosts scores for students with disabilities substantially more than the accommodation increases scores for non-disabled students.

A second approach to studying accommodations focuses on predictive validity, which provides information on how well a test predicts performance on some important criterion. For example, we may administer a mathematics test to predict how well individuals will fare in the future in advanced placement mathematics courses. In predictive validity studies of accommodations, therefore, we might administer the mathematics test in standard format and again with an accommodation. Then, we would compare how well scores in each test condition correspond with grades obtained in the future within advanced placement courses. A stronger relation for scores in the accommodated test administration would constitute evidence for the validity of the accommodation.

A third method for studying test accommodations involves the use of differential item functioning, which seeks to detect items that appear to be measuring differently for an identifiable subgroup of examinees. This constitutes evidence of bias when the source of differential difficulty is not relevant to the construct being measured by the test. Researchers, therefore, might apply differential item functioning on tests administered with and without accommodations for students with and without disabilities. Support for an accommodation would be provided when accommodated administrations remove sources of bias for students with disabilities, which are otherwise evident with standard administrations.

What Does the Literature Say?

It is interesting to note that the literature examining the validity of testing accommodations is limited. Most studies examine samples of convenience, which usually means post-secondary students taking the SAT or GRE. In addition, available research relies almost exclusively on the first methodological approach: differential effects. Below, we summarize some of the major findings from this literature.

EXTENDED TIME FOR READING AND MATHEMATICS ASSESSMENTS

Extended time is the most frequent accommodation used for students with LD. Unfortunately, the research base is small, with almost all studies conducted at the post-secondary level.

In *reading*, the database on extended time with post-secondary students has been conducted entirely by using the Nelson Denny Reading Test. This research provides contradictory evidence. And there are too few studies to sort out the effects of how researchers operationalized extended time. Moreover, in this literature using the Nelson Denny, sometimes students took advantage of additional time, and sometimes not. This suggests variations in the samples of students with respect to reading competence, and as documented in this literature, reading level may contribute to the effect of the extended time accommodation. In any case, it is difficult to generalize to school-age students with disabilities from studies conducted at the post-secondary level. Generalization is problematic because samples of students with disabilities participating in academic testing beyond high school may represent a self-selected group with higher overall skill levels than would be expected of the school-age population of students with disabilities. This is why research on school-age samples is critical for formulating decisions about the validity of testing accommodations for the elementary and secondary population of school-age learners.

Unfortunately, in the area of reading, only one study examined effects of extended time for school-aged children with and without disabilities; these children were in the fourth grade. Fuchs et al. (2000a) studied 400 students, who completed alternate forms of a reading assessment. Each form required students to read three passages and answer 24 multiple-choice questions (i.e., 8 questions per passage). In one administration, students had 12 minutes; in the other, 24 minutes. In addition, a subset of students completed alternate forms of the reading comprehension subtest of the Iowa Test of Basic Skills: one with standard time and one with 60 minutes. For each type of measure, test forms and order of administration were counterbalanced. So, in this study, students had extended, but not unlimited, time. On the 24-item measure, the size of the effects was nearly equivalent for 200 students with LD and 200 students without LD. Among the subsample of students (42 with LD; 29 without LD) who took the reading comprehension test of the Iowa Test of Basic Skills in standard form and with one or more accommodations including extended time, the size of effects again were fairly comparable for students with and without LD. Finally, for the smaller group of students who took the Iowa in standard and with the specific accommodation of extended time (16 students with LD and 11 students without LD), the size of effects were substantially larger for students without LD than for students with LD.

Consequently, in sum, the research based on differential boost with extended time for reading assessments with the school-age population is small. The Fuchs et al. (2000a) study indicates the need for caution about recommending the use of extended time as an accommodation for the population of students with LD when reading competence is being assessed because students with and without disabilities benefited similar amounts from extended time. This indicates that the extended time accommodation does not speak to anything essential about learning disabilities, but rather would benefit most students. Of course, this study only addressed students at the fourth grade.

In *mathematics*, research on the extended time accommodation is even more scarce than research involving reading tests. The studies are not only few, but also provide contradictory evidence. However, both studies conducted with school-age students (Fuchs, Fuchs, Eaton, Hamlett, & Karns, 2000; Munger & Loyd, 1991) indicate that extended time fails to produce differential boost for students with LD on conventional mathematics tests. It is possible, however, that differential boost is accomplished with measures of complex problem solving, which also require extended reading and writing demands (Fuchs et al., 2000b). Moreover, as with the reading studies of extended time, results suggest that extended time on mathematics tests may be related to individual students' level of mathematics competence: More competent students with LD may profit from differential time more than their less skilled peers. These findings, however, are preliminary. Additional research must be conducted before recommendations can be formulated concerning the use of extended time accommodations on mathematics or reading tests for the population of students with LD.

LISTENING ACCOMMODATIONS

Listening to text being read aloud is an accommodation that cannot preserve the construct validity of tests that measure reading competence. Consequently, we do not consider listening to, rather than reading, text as an accommodation for reading assessments. (This is the case even with reading comprehension tests; if someone else reads the text, then listening, not reading, comprehension is being assessed.) Moreover, the research base fails to consider a listening accommodation for domains other than tests of mathematics achievement. So, we review the research on listening accommodations as applied to mathematics tests, where three studies were conducted with school-age students.

In a large study with mixed results, Tindal, Glasgow, Helwig, Hollenbeck, & Heath (1998) carefully controlled opportunities for 2000 fourth-, fifth-, seventh-, and eighth-grade students in 10 states to hear text read on the North Carolina statewide assessment. Students with and without disabilities participated; those with disabilities were described only as special education. Each student took two alternate forms, each with 30 items, in standard format or with a videotaped reader. Colored highlights prompted students to identify text as it was read. In both conditions, students were permitted to use calculators, scratch pads, and rulers. Administration order was counterbalanced. Among fourth-grade students, effects were in the expected direction, with an interaction differentially favoring the benefits of video presentation among special education students. At the other three grade levels, however, no differential effect was demonstrated. At the fifth grade, effects were similar in size for special education and non-disabled students; at seventh grade, effects were smaller for special education than for non-disabled students (in the direction opposite from what was anticipated); and at the eighth grade, effects were again similar in size for special education and for non-disabled students.

Fuchs et al. (2000b) also identified mixed results, although the pattern of effects was more interpretable than in the Tindal, Glasgow, Helwig, Hollenbeck, & Heath (1998) study. Fourth graders (200 with LD and 200 without LD) took alternate forms of two types of tests in standard form and with an adult reading the text: a concepts and applications test and a mathematics problem-solving performance assessment in standard. For both types of tests, the test form and the administration order were counterbalanced. No differential effect was demonstrated as a function of students' disability status; that is, effects were of similar size of for both student types. This lack of differential effect for a conventional mathematics test echoes Tindal et al.'s findings among fifth, seventh, and eighth graders who also took a conventional concepts and applications mathematics test. By contrast, however, in the Fuchs et al. study, differential effects were documented on the problem-solving performance assessment, with larger effects for students with LD. The authors attributed this differential effect to the more extended reading demands associated with the performance assessment.

So, across Tindal, Heath, Hollenbeck, Almond, & Harniss (1998) and Fuchs et al.'s (2000b) studies, it appears that a listening accommodation on conventional mathematics tests does not promote differential benefits for students with disabilities. Nevertheless, two studies in the literature do provide contradictory evidence. Tindal, Heath, Hollenbeck, Almond, and Harniss (1998) examined a listening accommodation on a conventional mathematics test among 42 fourth-grade students in special education and 122 students in general education (no information on type of disability for the special education students was provided). Students were assigned randomly to a listening or reading condition, and a significant interaction between test condition and disability status was revealed. Effect sizes were larger for special education students and than for nondisabled students.

In another positive study, Weston (1999) administered two alternate forms of a mathematics test with calculation and word problems to 65 students with and 65 students without LD. One administration was standard, and the other provided a listening accommodation; the order of administration was counterbalanced. On calculation items as well as on word problem items, larger accommodation effects were identified for the students with LD. It is not clear why effect would accrue on calculation items where text reading is unnecessary. The author did comment that, "Much of the effect for learning disabled students occurs at lower reading levels where regular education students are not well represented in this study" (p. 9).

Across this set of four studies, it is difficult to draw conclusions about the use of reading text aloud on math tests to students with LD. On conventional mathematics tests, results are decidedly mixed: Some of the largest studies provide the basis for negative conclusions, with an absence of differential effects for having an adult read text aloud to students. On the other hand, other studies appear to document findings in which students with LD seem to profit differentially from having someone read the text surrounding mathematics items. Moreover, one study revealed that on assessments with more extended reading demands, students with LD may benefit differentially. In any case, studies are just beginning to accumulate. As with the extended time accommodations, recommendations about practice must await additional research.

OTHER ACCOMMODATIONS

A sprinkling of studies investigates other accommodations: marking answers directly on test booklets (rather than on bubble sheets); use of large print on reading tests; calculator accommodations on mathematics tests; and providing students with opportunities to read reading tests aloud (rather than silently). For each of these accommodations, only one study is relevant. So, in each case, findings are preliminary, and conclusions await further study.

One study investigated how *marking responses directly on tests*, rather than requiring students to indicate their answers on bubble sheets, affects students' scores. Tindal, Heath, Hollenbeck, Almond, & Harniss (1998) examined effects for fourth-grade special and general education students on reading and math tests. Each student took two administrations of each test; counterbalancing was employed. In reading, 130 special education students and 136 general education students participated. Regardless of disability status, students actually scored higher with the bubble sheets. Results were similar in math among 128 special education and 120 general education students, with only small effects for either type of student.

Fuchs et al. (2000a) examined the use of a *large print* accommodation among 200 fourth graders with LD and 200 fourth graders without LD on two alternate forms of a reading test, each of which required students to read three passages and answer eight questions per passage. Passages and order of administration were counterbalanced. Results failed to support the notion of differential boost: Effect sizes were similar for students with and without LD.

In the same study, Fuchs et al. (2000a) examined the utility of *having students read aloud instead of silently on reading tests*. The same 200 fourth-grade students with LD and 200 fourth-grade students without LD completed a standard administration of the reading test that required students to read three passages and answer eight questions per passage. Each student also took an alternate test form, in which students read aloud. Passages and order of administration were counterbalanced. Differential boost was demonstrated in this study; effect sizes of were larger for students with LD than for students without LD. Consequently, preliminary evidence suggests that, on average, having students with LD read aloud instead of silently may serve to level the playing field on tests that measure students' reading competence.

Fuchs et al. (2000b) investigated the use of *calculators* among fourth graders with ($n = 200$) and without ($n = 200$) LD. First, each student took two alternate forms of a math concepts and applications test, one in standard format and one with a calculator; test order and form were counterbalanced. Then, each student took a math problem-solving performance assessment, one in standard format and one with a calculator; again, test order and form were counterbalanced. On concepts and applications, the use of the calculator depressed scores for students with and without disabilities. Both types of students scored better without a calculator; the size of this effect was similar for students with and without LD. On the performance assessments, findings differed. Calculators again depressed scores for students without LD; by contrast, they increased the scores of students with LD. Of course, the effect for students with LD was negligible, and the interaction between students' disability status and administration condition only approached statistical significance.

BEST PRACTICE IN IDENTIFYING FAIR AND APPROPRIATE ACCOMMODATIONS FOR STUDENTS WITH DISABILITIES

The research base is lean and limited to one approach to the study of testing accommodation: differential effects across students with and without disabilities. Consequently, at this time, it is not possible to formulate conclusions about the validity of testing accommodations for students with disabilities. Of course, even if we could point to a well-established literature that documented differential effects for students with LD, then the research would represent average performances. And because students with LD demonstrate a variety of underlying deficits, tremendous heterogeneity exists in the population. This means that many students with LD do not conform to "average" findings in the research literature. In fact, although some accommodations may ultimately reveal differential "average" effects, some students with LD will fail to benefit from those accommodations. In the same way, although some accommodations may eventually fail to demonstrate differential "average" effects, some students with LD undoubtedly will profit from those very accommodations substantially more than non-disabled students. For this reason, individual diagnosis of appropriate accommodations is necessary for students with LD.

Consequently, over the past 4 years, we have developed and studied an assessment tool school psychologists and teachers can use to supplement informal judgments about whether an individual student with LD should be awarded a specific accommodation. We call this tool the Dynamic Assessment of Test Accommodations, or DATA. With DATA, teachers administer alternate forms of short tests under varying conditions: in math computation, standard and extended time; in math concepts and applications, standard, extended time, calculator, and an adult reading text; in math problem solving, standard, extended time, calculator, an adult reading text, and an adult writing students' nonmathematical responses on request; and in reading, standard, extended time, large print, and students reading aloud. For each student with LD, within each domain (i.e., math computation, math concepts and applications, math problem solving, and reading), the teacher calculates the size of the accommodation boost (i.e., score with the accommodation minus score in the standard format). Then, the teacher compares the individual student's boosts with normative information on non-disabled students. When a student with LD derives an accommodation boost that substantially exceeds the boost we expect for non-disabled students, DATA recommends that the IEP team consider the accommodation for classroom tests and for the statewide assessment. Research conducted with DATA is promising. Results for math and reading are similar. In this chapter, we provide an overview of the reading study (Fuchs et al., 2000a). See Fuchs et al. (2000b) for information on the math study.

Participants

Participants were 365 children. Most were in fourth grade. Approximately half of these students had no identified disability, and the other half had a LD. To each student we administered DATA in the area of reading. Therefore, brief assessments were conducted under four conditions: standard (4 minutes per passage, regular-size print, student reads silently) and extended time (8 minutes per passage), large print, and student reads aloud. With DATA, students read three passages for each of the four forms. For each passage, they answer eight multiple-choice questions: six literal questions focusing on four main ideas and two details, along with two inferential questions. On each passage, students have 2 minutes to read and 2 minutes to answer questions; with extended time, 4 minutes to read and 4 minutes to answer questions is permitted. Scores are corrected for guessing (number correct minus [number incorrect/3]) and then averaged across the three passages.

In this study, we used the scores on the four brief assessments within DATA in the following ways. First, we used the sample of students with*out* LD to estimate the "typical" boost we might expect for each accommodation from non-disabled students. Then we compared the accommodation boost of each individual student with LD to the "typical" boost to determine whether the individual demonstrated a greater-than-expected boost and therefore qualified for that accommodation on the large-scale assessment. We compared accommodation decisions based on DATA to the decisions teachers had formulated using their judgment.

Finally, to each student with LD, we administered two forms of a large-scale reading assessment (the Iowa Test of Basic Skills) under standard and accommodated conditions, with test forms and administration orders counterbalanced. We examined how well teacher and DATA decisions corresponded to the accommodation boosts students experienced on the Iowa.

How Well Do Teacher Judgments About Accommodations Correspond to the Dynamic Assessment of Test Accommodations Decisions?

We found poor correspondence between the decisions formulated by teachers and by DATA. Teachers awarded many more accommodations (73% for teachers versus 41% for DATA). Moreover, students to whom teachers had awarded accommodations failed to earn greater accommodation boosts than did students to whom teachers had denied accommodations. In fact, effect sizes were minimal. Boosts were larger for teacher denials than for teacher awards for two of the three accommodations.

This calls into question the accuracy of teacher judgments in specifying testing accommodations. Also, the accuracy of teacher judgments is especially important in light of the demographic markers and performance variables associated with teachers' decisions. Specifically, in our research, the students whom teachers had selected for accommodations had been retained in school more years, disproportionately were African-American and received reduced or free lunch, and had lower IQs and reading instructional levels. Importantly, no such differences were associated with the decisions formulated with the DATA-based method.

Did DATA Enhance Teachers' Accommodation Decisions?

So, which method for identifying accommodations better predicted the boosts students earned on the large-scale assessment? We dedicated the final phase of our study to answering this question. This final study phase was limited to students with LD, with whom we conducted two forms of a commercial test used for large-scale assessments: the Iowa Test of Basic Skills. Students completed one form in standard format. For the other form, they received the accommodation(s) specified by DATA or, if DATA had ruled out all accommodations, they received a randomly assigned accommodation.

The accommodation boosts on this commercial test revealed the potential for DATA to supplement and enhance teacher judgments. Accommodation boosts did not correspond to teachers' judgments about whether students did or did not warrant accommodations. The main effect for teacher judgment failed to achieve statistical significance. In fact, students to whom teachers had *denied* accommodations actually earned somewhat *larger* accommodation boosts than did the students to whom teachers had awarded accommodations.

By contrast, the main effect sorting students into DATA-based decisions did achieve statistical significance. Students to whom DATA had awarded accommodations earned larger boosts as a function of having those accommodations when compared to the subset to whom DATA had denied accommodations.

Consequently, teachers granted accommodations to large numbers of students with LD who failed to profit from those accommodations more than would be expected among non-disabled students. DATA was, however, helpful in sorting students into those who did and those who did not profit differentially from accommodations.

Among the students to whom teachers had awarded accommodations, accommodation boosts of students to whom DATA had awarded accommodations were 2.81 times higher than those to whom DATA had denied accommodations. This substantial benefit illustrates how DATA differentiated true from false positives. Of course, reducing false positive accommodation decisions is critical. One important goal of including students with disabilities in accountability databases is to prompt schools to use their resources to enhance outcomes for all students, including those with disabilities. If this is to occur, then test scores must provide realistic, not inflated, estimates of student capacity so that schools can use accountability databases to identify which students with disabilities require additional attention. In fact, when accommodations produce spuriously high scores, schools experience reduced pressure to intervene on behalf of students with disabilities.

In a similar way, if we take the subgroup of students to whom teachers had denied accommodations and we further divide those students into the ones to whom DATA had and had not awarded accommodations, we see a 17.52-fold increase in accommodation boost between DATA-based decisions. Therefore, DATA was useful in sorting the group of students to whom teachers had denied accommodations into two subsets: those who did and those who did not benefit differentially. The implications of denying accommodations to students, when those accommodations are warranted, are serious. Without accommodations, these students may be disallowed the opportunity to demonstrate the mathematical problem-solving competence they possess. And, when high-stakes consequences for individual students are associated with participation in accountability systems, it is essential for students to be permitted the test accommodations their disabilities warrant.

Conclusions

This study, as does a parallel investigation in math (Fuchs et al., 2000b), calls into question teacher judgment about test accommodations. Teachers' decisions do not correspond to students' actual accommodation boosts on the brief assessments or on the longer, large-scale, commercial test. Moreover, teachers' decisions appeared to be influenced by demographic and performance variables that were not associated with more objective methods for determining accommodation decisions.

These findings may not be surprising. After all, federal legislation requiring test accommodations to facilitate student participation in large-scale testing programs is new, and teachers have limited experience in formulating these decisions. They also have little conceptual background about the function of test accommodations, no formal opportunities to compare the actual effects of test accommodations for students with and without disabilities, and a scant literature base to consult as they seek information to help inform their decisions.

Although the shortcomings of teacher judgment may be understandable, findings do nevertheless provide the basis for concern. Fortunately, this study also demonstrates how objective data sources, such as DATA, can supplement teacher judgments to enhance accommodation decisions. School psychologists are the professional group in schools with the most sophisticated knowledge about measurement and assessment. This makes school psychologists the ideal person for helping teachers operationalize their state's testing accommodations and putting into place objective methods for identifying which students should be awarded test accommodation. DATA is one well-developed tool psychologists can use to formulate these decisions.

SUMMARY

Test accommodations are one critical feature for promoting the valid participation of students with disabilities within standards-based reform. Unfortunately, research provides little guidance to practitioners as they struggle to formulate decisions about which students should be permitted which test accommodations. And research suggests that teachers award too many accommodations, which fail to preserve validity. School psychologists are the professionals with the greatest expertise for guiding IEP teams toward sound decisions. The Dynamic Assessment of Test Accommodations is one well-developed tool school psychologists can use to foster objective decision making about test accommodations.

ANNOTATED BIBLIOGRAPHY

Fuchs, L. S., Fuchs, D., Eaton, S., Hamlett, C. L., Binkley, E., & Crouch, R. (in press). Using objective data sources to supplement teacher judgment about reading test accommodations. *Exceptional Children.*

This study describes how the Dynamic Assessment of Test Accommodations can facilitate more appropriate decisions about accommodations for reading tests. It also reports effects for students with and without disabilities for three types of test accommodations: extended time, large print, and students reading aloud.

Fuchs, L. S., Fuchs, D., Eaton, S., Hamlett, C. L., & Karns, K. (2000). Supplementing teachers' judgments of test accommodations with objective data sources. *School Psychology Review, 36*, 65–85.

This study describes how the Dynamic Assessment of Test Accommodations can facilitate more appropriate decisions about accommodations for mathematics tests. It also reports effects for students with and without disabilities for one type of computation test accommodations (extended time), for three types of concepts/ applications accommodations (extended time, calculator, adult reading aloud), and for four types of math problem-solving accommodations (extended time, calculator, adult reading aloud, adult writing nonmathematical responses for students).

Fuchs, L. S., Fuchs, D., Eaton, S., & Hamlett, C. L. (2000). *The Dynamic Assessment of Test Accommodations.* San Antonio: Psychological Corporation.

The Dynamic Assessment of Test Accommodations is an instrument for supplementing teacher judgments about test accommodations.

Phillips, S. E. (1994). High-stakes testing accommodations: Validity versus disabled rights. *Applied Measurement in Education, 7*(2), 93–120.

This article provides an overview of considerations about the validity of test accommodations.

Tindal, G., Heath, B., Hollenbeck, K., Almond, P., & Harniss, M. (1998). Accommodating students with disabilities on large-scale tests: An empirical study of student response and test administration demands. *Exceptional Children, 64*, 439–450.

This study reports findings of controlled investigations of two test accommodations: marking responses directly in test booklets (instead of using bubble sheets) for reading and math tests and having an adult reader for math tests.

Which Best Practices Will You Use Today?

School psychology is one of the most dynamic professions in mental health or education today. The emphasis on prevention, early intervention, accurate assessment, collaboration, and problem solving requires school psychologists to be creative thinkers who command a tremendous range of evidence-based knowledge. Keeping up with best practices is critical.

For nearly two decades, NASP's ***Best Practices in School Psychology*** volumes have served as the profession's primary reference on the core body of knowledge regarding children's healthy learning and development. This latest two-volume edition, ***Best Practices in School Psychology IV***, brings that expertise into the 21st Century to help school psychologists successfully manage today's complex challenges in service to students, families, and schools. ***BPIV*** updates and expands on ***BPIII*** to reflect changes in:

- Theory, research, and practice
- Expectations and role within schools
- Needs and diversity of students, families, and educators
- Collaboration and communication with other stakeholders
- Assessment and intervention strategies
- Laws, funding, and public policy
- Mental health and education systems
- Training and professional standards

As earlier ***Best Practices*** editions did, ***BPIV*** melds theory, research, and practice to provide a thorough yet concise discussion of a broad range of relevant issues. Well over 100 leading experts contributed to the 101 new or revised chapters, organized in a functional two-volume set. Each chapter delivers an overview of an important topic, puts it into a professional context, offers practical strategies, and recommends additional resources. No other single resource enables you to quickly place so many topics into perspective and competently integrate them into your daily work.

All 101 chapters are completely revised or brand new!

An indispensable resource for practitioners, researchers, trainers, and students!

58 Best Practices in Promotion of Social Competence in the Schools

Kathy McNamara
Cleveland State University

OVERVIEW

In 1986, Good and Weinstein presented a case for a comprehensive view of school effectiveness, arguing that emotional, social, and moral capacities must join intellectual capacity as proper targets for the educational mission of schools:

> School is a place where children develop or fail to develop a variety of competencies that come to define self and ability, where friendships with peers are nurtured, and where the role of community member is played out, all during a highly formative period of development. Thus, the building of self-esteem, interpersonal competence, social problem-solving skills, responsibility, and leadership becomes important both in its own right and as a critical underpinning of success in academic learning (Good & Weinstein, 1986, p. 1095).

The term "social competence promotion" (SCP) refers to institutional efforts to accomplish this mission, combining the goals of prevention and competence building with problem-focused interventions (Hoagwood & Erwin, 1997). The importance of SCP extends beyond the school years; adaptability, personal management, group effectiveness, teamwork, negotiation, and organizational effectiveness have been cited by potential employers as competencies that are at least as important as academic skills for success in the workplace (Elias et al, 1997).

The magnitude of the challenge facing SCP initiatives is reflected in the range of problems they are expected to prevent and remedy, including school safety concerns, gang membership, academic failure and school dropout, substance abuse, delinquency, youth violence and weapons possession, bullying, sexual harassment, and mean-spirited teasing (Walker et al., 1998). With increasing interest in school-based SCP programs as a response to these concerns, a window of opportunity has been opened for school psychologists to actualize their potential as mental health professionals knowledgeable about programs, interventions, and resources, and how to integrate them into the culture of schools (Nastasi, 1998).

Unfortunately, the many school-based programs and activities that comprise SCP are often provided in a piecemeal manner, with little or no organization or coordination of various program elements, and inadequate evidence of their likely or actual effectiveness. Even those programs deemed effective seldom demonstrate a meaningful impact on attitudes and behaviors identified as critical by the larger community (Masten & Coatsworth, 1998; Walker et al., 1998). Clearly, there is a need to conceptualize and plan school-based SCP programs as a coordinated system of activities where effectiveness has been validated through research and systematic evaluation. Moreover, programs should match the nature, frequency, and intensity of activities and interventions to the differing needs of students, whether on the basis of developmental considerations, student risk status, or the "severity and intractability of students' adjustment problems"

(Walker et al., 1996, p. 196). Success in building a comprehensive SCP program requires a commitment to infusing its goals and principles into the fabric of the school's organization and daily activities; that is, in other words, into the culture of the school.

The role of the school psychologist varies with each element of SCP programs, from disseminating research findings about risk factors and intervention techniques to developing and conducting screening activities. This chapter provides a conceptual framework for comprehensive school-based SCP program development, including important goals and recommended elements, and includes information about several projects whose success has been documented through research.

BASIC CONSIDERATIONS

Factors Affecting the Development of Social Competence

Research has identified three major influences on the development of social competence: *early life experiences*, *social-contextual factors*, and *school experiences*. In contrast to those who have developed adequate self-regulatory skills by the time of school entry, children who have learned maladaptive behavior patterns in their early years often bring these patterns to school in the form of aggressive and antisocial behavior (Patterson, DeBaryshe, & Ramsey, 1989). Parenting practices that have been linked to conduct problems among school-aged children include inconsistent and harsh discipline, low supervision and involvement, and inflexible rigid discipline (Conduct Problems Prevention Research Group, 1999a). "Early starters," or children exposed since infancy to ineffective parenting practices resulting from disruptive family environments or stressors, are at substantial risk for later school dropout and delinquency (Walker, Colvin, & Ramsey, 1995).

Social-contextual factors also affect the development of social competence; among such factors, the Conduct Problems Prevention Research Group (1999a) cite family poverty, family instability, and factors negatively affecting child development, such as criminal victimization of the family, greater number of siblings, and high residential mobility. Children with more stable and advantaged backgrounds typically are exposed to the kinds of literacy-related experiences that facilitate reading and academic achievement in the early school years, and are more likely to receive active monitoring and reinforcement of prosocial behaviors and skills (Walker et al., 1995). Although many contextual factors are not amenable to intervention (particularly by schools), it is important to recognize their cumulative contribution to children's risk for social competence deficits, and to address their effects in prevention and intervention programs.

Schools, as critical socializing institutions, exert profound and lasting influence on children's social competence (Hawkins & Weis, 1985). The explicit curriculum of schools specifies desired attitudes and skills, as well as methods for their attainment, while the implicit curriculum—conveyed in a more subtle manner through rules, enforcement methods, instructional practices, interpersonal interactions, forms of student participation in decision making, and home-school communication—teaches attitudes and skills through modeling and children's own experiences. Many aspects of children's classroom experience influence the development of social competence; these are displayed in Table 1.

Goals of Social Competence Promotion Programs

SCP programs first need to define an intended scope of influence, a task made difficult by the extremely broad conceptualizations of social competence. For example, Masten and Coatsworth (1998) identified three "hallmarks of success" for children during the school years: (a) social competence with peers, (b) socially appropriate conduct, and (c) academic achievement. Walker et al. (1983) view school-aged social competence as the ability to recruit social networks, to meet the demands of teachers (who control classrooms) and peers (who control playgrounds), and to adapt to changing conditions in one's environment. While all of these competencies can be addressed in different ways by SCP programs, planners should ensure that a school program has several explicit goals that are consistent with the school's stated philosophy or mission. For example, a school that has adopted academic achievement and good citizenship as priorities might articulate such SCP goals as "personal responsibility and self-discipline in working toward a standard of academic excellence" and "active and capable participation in individual and group decision making."

Table 1. Classroom variables affecting children's social competence

Variable	*Desirable features*
Teacher expectations for academic and social performance	Explicit, unambiguous, challenging; accommodating differences
Teacher use of authority	Context-appropriate display of authoritative, democratic, or laissez-faire styles; avoidance of authoritarian control; availability of choice
Development, nature, and enforcement of rules	Student participation in rule development; clear, limited number; observable behaviors; consequences for violations consistently applied
Management of time	Task-relevant time promoting student engagement; smooth transitions; generally predictable but flexible schedule
Use of space	Desk and workspace arrangements consistent with task demands; teacher proximity to students to enable monitoring and encouragement
Goal structure	Flexibility in use of individualistic, cooperative, and competitive goals
Instructional context	Variety of one to one adult-student, small/large groups, peer-assisted, independent, and cooperative work
Nature of tasks	Challenging and stimulating; promoting active engagement; incorporate student interests/skills; minimal use of worksheets for drill and practice
Monitoring of student behavior and performance	Frequent observation and feedback to students; acknowledgment of positive achievement; ongoing assessment by using objective measures sensitive to small changes in performance; encouragement of self-regulation among students
Behavior management strategies	Reactive strategies (punishment, timeout, etc.) used sparingly; emphasis on proactive strategies (contingency plans, goal-setting); minimal use of class time to manage misbehavior; consequences stress alternative behavior and problem solving; students participate in classroom management (e.g., class meetings, conflict mediation)

Source. Adapted from Campbell and Siperstein (1994).

Although planners may be tempted to focus on narrow goals because of recent circumstances or events (e.g., violence prevention in the wake of highly publicized school shootings), it is important to identify broad outcomes that can be attained through a range of components touching on many aspects of children's school experience. For example, a goal might specify "effectiveness in managing personal and interpersonal conflict in a peaceful and respectful manner," rather than "elimination of weapons from the school environment through conflict mediation and a zero tolerance policy." In this way, the school can avoid the fate of many SCP programs that are abandoned when they fail to have an immediate impact on narrowly construed goals, when resources for a specific activity are withdrawn (especially when no institutional "ownership" of the activity has been cultivated), or when the fanfare surrounding a particular bandwagon issue or approach fades.

It is also important to understand the difference between *social competence* and *social skills*. Social skills are the specific strategies and behaviors used to accomplish social tasks such as making requests, making friends, and initiating interaction. Socially skillful behavior is presumed to lead to social competence, which refers to the overall effectiveness and positive social impact of an individual's behavior (Walker et al., 1995). This distinction is important because an effective SCP program requires more than the adoption of a specific social skills training program. It is reflected in many aspects of the school culture, including disciplinary policies, teaching practices, and decision-making procedures. The yardstick for the success of a school's SCP program is the extent to which administrative and instructional practices support the development and display of socially competent attitudes and behavior among students.

School psychologists with training in organizational consultation are especially well prepared to assist school administrators in the process of setting goals that are consistent with the school's stated philosophy, are responsive to community needs, and are sufficiently broad to accommodate a number of specific objectives. Though administrators and teachers may be inclined to bypass planning stages in their eagerness to adopt curricula or plan activities, school psychologists can help them to understand the importance of goal-setting. A set of comprehensive goals devised by members of the school community elicits support for subsequent implementation efforts, legitimizes the use of school resources for SCP activities, assures that a variety of needs is addressed, and serves as a benchmark for program planning and evaluation.

BEST PRACTICES

Elements of School-Based Social Competence Promotion Programs

In contrast to typical practice, which defines social competence promotion in terms of a particular curriculum or program offered in the school, best practice requires a broad conceptualization of social competence as a goal toward which a variety of activities and experiences is directed. Walker et al. (1996) identified four school-based systems in which SCP might occur. The *school-wide system*, which addresses the general school population, establishes school climate or culture through rules and standards for performance, organizational features and practices, and priorities for instructional activities. A *specific setting system* governs behavior in the common areas in which students spend time daily (e.g., cafeteria, playground, buses). The *classroom system* is largely under the control of teachers, who establish and enforce policies and procedures within an instructional setting. Finally, the *individual student system* provides direction for responding to the needs of students who present problematic behavior. SCP programs reflecting best practice will incorporate program elements in each of these four systems.

A comprehensive approach to SCP is based on models of effective prevention, which incorporate three broad functions in program goals and activities. *Primary prevention* is reflected in academic instruction, training for all children in an array of social problem-solving skills, enhancement of school and classroom climate, extracurricular activities, and teaching and disciplinary practices that confer and promote social and personal responsibility. *Secondary prevention*, which targets children at risk for problematic social adjustment, includes early screening and intervention (including social skills training) to interrupt negative behavior patterns and address skill deficits, enforcement of disciplinary policies for infractions of rules, activities to draw at-risk children and youth into the conventional mainstream, and supportive services to families experiencing acute or chronic disruption. *Tertiary prevention* seeks to minimize the harmful impact of established social adjustment problems, and includes academic remediation, training in survival and social skills such as anger management and self-control, career and vocational training, and efforts to reduce the likelihood of school dropout.

Often, schools' SCP efforts consist of primary prevention initiatives (e.g., drug and alcohol awareness programs, weekly lessons drawn from a social skills curriculum), which are offered to students across a wide range of ages, coupled with tertiary prevention activities (e.g., tutoring students with academic deficiencies) aimed at older students with well-established patterns of problem behavior. Drawing on the research literature about effective prevention, school psychologists can emphasize the need for a fit between levels of prevention and student characteristics, such as age, risk status, and developmental levels (McNamara, 1995). For example, a school psychologist, knowing that early intervention is essential for meaningful behavior change, might offer to work with primary grade level teachers to develop classroom interventions for use with children displaying antisocial behavior patterns.

By now, it should be clear that SCP programming is a broad undertaking extending far beyond choosing a social skills curriculum for the primary grades or training a select group of students to serve as peer mediators. A review of the research literature reveals eight major objectives for school-based SCP programs (see Table 2). In the following section, each of these objectives is accompanied by a description of corresponding program elements.

Objectives for Program Design

IDENTIFY CHILDREN AT RISK FOR SOCIAL PERFORMANCE DEFICITS AT THE POINT OF SCHOOL ENTRY

Children whose early life experiences socialize them into negative behavior patterns (i.e., early starters) are unable to make a successful transition to school, where they find it impossible to meet expectations for prosocial behavior and self-management under conditions of greater structure. Ultimately, their problematic behavior leads to rejection by teachers and peers, a condition that is a powerful predictor of later, more severe, life problems (Walker et al., 1995). Although research demonstrates that intervention before age 9 is crucial to effect meaningful change in the patterns of problem behavior exhibited by these children, most school-based programs bypass younger children in the mistaken belief that children will outgrow these negative patterns, reserving intervention resources for pre-adolescents and adolescents. Intervention at younger ages has a greater likelihood of success, but requires a reliable method for identifying children in need of services (Conduct Problems Prevention Research Group, 1999b). A system for screening children for behavior problems in kindergarten or first grade is an important secondary prevention component of a comprehensive SCP program. With widely acknowledged expertise in assessment, school psychologists might contribute to early screening activities by suggesting specific instruments and procedures, providing accurate interpretations of screening results, and supporting appropriate interventions linked to assessment findings.

Several instruments are available for screening purposes, including the Student Risk Screening Scale (Drummond, 1993), which consists of seven items that are rated on a 3-point scale, and can be used by teachers to evaluate large groups of children. Items included in the scale assess stealing; lying, cheating, and sneaking; behavior problems; peer rejection; low academic achievement; negative attitude; and aggressive behavior. The Child Behavior Checklist (Achenbach, 1991) is recommended by Walker et al. (1995) as another instrument that can detect early patterns of antisocial behavior. They describe a screening process in which teachers nominate children whose behavior matches a profile consisting of rule violations, aggression toward others, damaging or destroying property, taking things without permission, and a sullen, agitated emotional state. Teachers and parents then rate the behavior of these students on the aggression subscale of the Child Behavior Checklist. Children whose scores on either teacher- or parent-rating forms fall two or more standard deviations above the subscale mean are considered to be at risk for serious antisocial behavior problems.

The nature and extent of early intervention efforts vary with children's needs and setting characteristics. However, programs such as First Step to Success, available from the Institute on Violence and Destructive Behavior at the University of Oregon, have demonstrated their effectiveness and serve as models for identification and intervention. First Step is designed to divert young children (grades K–2) from problematic behavior patterns through a systematic and collaborative process involving teachers, parents, and "coaches," or consultants. The program is implemented across a 2- to 3-month period in both kindergarten and home settings, providing opportunities for children to learn adaptive patterns of school behavior and for training parents to teach children skills contributing to school success. The classroom component involves monitoring and reinforcing children's prosocial behavior, with signals to indicate the appropriateness or inappropriateness of behavior. The home component teaches parents about a set of six skills that children need to master for success in school: communication and sharing at school, cooperation, limit-setting, problem solving, friendship-making, and developing confidence. Consultants teach one skill per week to parents during hour-long sessions held in the home. Lessons include materials

Table 2. Objectives for school-based social competence promotion programs

- Identify children at risk for social performance deficits at the point of school entry.
- Provide appropriate and intensive intervention to children displaying problematic behavior patterns.
- Develop discipline policies that emphasize rehabilitation over punishment, that provide clear guidelines for behavior, and that are enforced in a consistent and even-handed manner.
- Promote caring and stable interpersonal relationships between students and adults.
- Modify instructional practices to increase active engagement in learning.
- Offer frequent opportunities for students to learn and demonstrate socially responsible behavior.
- Support the role of families in promoting social competence.
- Evaluate the impact of program activities.

and strategies that parents can use to provide opportunities for children to practice newly learned skills (Golly, Stiller, & Walker, 1998).

PROVIDE APPROPRIATE AND INTENSIVE INTERVENTION TO CHILDREN DISPLAYING PROBLEMATIC BEHAVIOR PATTERNS

It is beyond the scope of this chapter to provide a detailed review of principles underlying effective interventions for children's problematic social performance. However, Walker et al. (1995) have furnished several guidelines pertaining to the structure and delivery of such interventions in school-based SCP programs (see Table 3). First, they recommend that intervention planning occur in context of an individualized, functional assessment of behavior. The purpose of this assessment is to identify the purposes of problematic behavior; that is, what the child intends to accomplish through the behavior, as well as environmental conditions affecting the occurrence of the behavior (e.g., rules or standards for behavior, teacher demands for academic and social behavior, enforcement methods, difficulty level of materials and activities). The process of functional assessment yields information useful in planning behaviorally based intervention approaches, which have been found to be more effective than other, non-behavioral approaches in producing significant positive outcomes (Gottfredson, 1997). Moreover, documentation of behavior intervention plans based on the results of functional behavior assessment may be needed to satisfy the requirements of the Individuals with Disabilities Education Act (1997) for children with disabilities whose behavior interferes with their ability to learn.

Second, interventions for problems related to social competence should always include strategies to promote empathy and responsible decision making, since these keystone skills are frequently deficient among children displaying inappropriate and antisocial behavior. The Positive Peer Culture program described by Vorrath and Brendtro (1985) emphasizes the development of these skills through student participation in small groups (led by adult facilitators, such as school psychologists) where members employ problem-solving methods in a mutual assistance framework.

Third, interventions should promote positive, alternative ("replacement") behaviors that are at least as efficient as the behaviors they are intended to replace. That is, alternative behaviors should be successful in accomplishing the child's purposes at (what the child perceives to be) an equal or lesser cost. For example, a child who employs aggressive behavior to gain a sense of power and control over others might be taught to exercise leadership in a classroom activity. The child will likely adopt the proposed alternative as long as he or she regards it as effective in attaining a sense of power, and does not believe that it will require resources or skills beyond his or her own ability to perform. Equally significant, the "cost" of a behavior also must be assessed in terms of any potential, negative consequences of the new behavior (again, as perceived by the child). If the child fears that classroom leadership activities will elicit teasing from peers, then this alternative to aggressive behavior is likely to be rejected.

Fourth, Walker et al. (1995) advise that only positive strategies be employed at the outset of an intervention plan (e.g., social skills training, limit setting, daily debriefings about problems encountered, self-monitoring, re-statement of rules, incentives), with the addition of aversive strategies (e.g., timeout, suspension, removal of privileges) only if positive strategies fail to produce desired effects.

Table 3. **Guidelines for intervention with students displaying problematic behavior patterns**

- Use functional behavior assessment as basis for planning interventions.
- Include strategies to promote empathy and decision making.
- Promote functionally equivalent (positive) replacement behaviors.
- Employ only positive strategies at onset, adding negative strategies only if necessary.
- For group interventions, include positive peer models.
- Involve primary caregivers in interventions.

Source. Walker et al. (1995).

Fifth, interventions that are delivered in a group format should provide for participation by peers who demonstrate positive and skillful social behavior, since their participation keeps the group from assuming a negative identity and enables them to serve as models of positive behavior and prosocial attitudes. In this way, the (inadvertent) negative and damaging effects of segregating children for intervention with similarly troubled peers can be avoided (Gibbs, Potter, Goldstein, & Brendtro, 1996; McNamara, 1996; Vorrath & Brendtro, 1985).

Sixth, Walker et al. (1995) recommend that planners attempt to involve primary caregivers in interventions, even when they are reluctant to participate in planning or implementation activities.

Social skills training programs are perhaps the best-known component of school-based SCP efforts (see Gresham's chapter on social skills, this volume). Miller, Brehm, and Whitehouse (1998) cite research indicating that social-cognitive deficits play a significant role in the development of socially problematic behavior over time, and that such deficits reveal themselves in poor problem solving, misjudgments about social situations, and inadequate strategies for managing conflict situations. Efforts to correct these deficiencies cannot be limited to students' participation in the social skills curriculum offered in a preventive context to all students; instead, individually tailored interventions addressing specific social skill deficits must be implemented. By recommending appropriate procedures for assessing social skills, school psychologists can help educators avoid the "one size fits all" approach to social skills training that is especially inappropriate as the secondary prevention intervention needed by at-risk students.

Jones, Sheridan, and Binns (1993) describe a school-wide social skills assessment and training model that provides in-class social skills training for all students and intensive small group training for at-risk students. They review a number of assessment procedures, including direct observation, teacher and parent rating scales, sociometrics, self-report of social skills, teacher and parent interviews, and child interviews. Walker et al. (1995) offer an assessment procedure in which classroom teachers identify social skill problems by using a matrix to rate students across a set of core social skills, including listening, greeting others, joining in, complimenting, expressing anger, keeping friends, doing quality work, following rules, using self-control, offering assistance, disagreeing with others, being organized, and having conversations. The resulting matrix can be examined at several levels:

1. To determine the overall skill level of the class and whether specific skills represent deficiencies for a number of children.
2. To discover sub-groups of children displaying similar skill deficiencies.
3. To identify children who are deficient in a number of core social skills.

Screening results can be used to plan instructional activities, whether for the entire class, for sub-groups of children with similar skill deficiencies, or for individual children requiring more intensive remedial interventions. The Social Skills Rating System (Gresham & Elliott, 1990), a formal instrument designed to evaluate children's social skills for purposes of intervention planning, allows teachers to rate a set of social skills according to their frequency of occurrence, as well as perceived importance of the skill.

Gresham (1986) distinguished between problems arising from skill deficits and those attributable to performance deficits, observing that this distinction is critical to successful intervention efforts. Problems arising from a failure to perform a known skill—or non-fluent performance of the skill—should be addressed through motivational strategies and increased opportunities for practice. Skill deficits, on the other hand, require instructional intervention. For individual children, a functional assessment should be used to reveal whether problems represent a failure to have learned the desired behavior (skill deficit) or a failure to display an already-learned behavior (performance deficit). Commercially available programs for teaching social skills include the PREPARE Curriculum (Goldstein, 1988), Aggression Replacement Training (Goldstein & Glick, 1987), and Social Decision Making and Life Skills Development (Elias, Friedlander, & Tobias, 1995).

DEVELOP DISCIPLINE POLICIES THAT EMPHASIZE REHABILITATION OVER PUNISHMENT, THAT PROVIDE CLEAR GUIDELINES FOR BEHAVIOR, AND THAT ARE ENFORCED IN A CONSISTENT AND EVEN-HANDED MANNER

A set of core features characterizing effective discipline policy has been identified by a number of researchers (See Table 4). These features include (a) clear communication of rules and expectations for student behavior, (b) willingness to act immediately to deliver appropriate consequences when rules are broken, (c) monitoring of the behavior of students as a group, and (d) a system through which positive behavior is recognized on a routine basis (Gettinger, 1988; Hawkins & Lam, 1987; Mayer, 1995). At an institutional level, Walker et al. (1995) observe that the success of a school discipline policy depends on (a) the presence of strong leadership, (b) commitment on the part of school staff, (c) guidelines specifying circumstances in which administrators (versus teachers) should manage problem behavior, (d) staff development and training, (e) data management and evaluation allowing record keeping for disciplinary actions and outcomes, and (f) structures allowing for periodic evaluations and revisions of the policy.

Walker et al. (1995) describe five general phases in planning a school-wide discipline policy. The first phase requires school staff and other members of the school community to reach agreement or consensus about the basic purposes of the disciplinary policy. A review of the goals that have been articulated for the schools' SCP program can help guide this process. Next, expectations for behavior should be specified, including examples of appropriate and inappropriate behavior related to each expectation. It is important for a school-wide discipline policy to also specify expectations for unique or potentially problematic settings (e.g., cafeteria, buses, library). In the third phase, a plan is devised for teaching students the agreed-upon expectations for behavior (i.e., practices for acknowledging positive behavior; informal instruction in expected behaviors, including reminders, supervision, and feedback; and formal instruction in expected behaviors, including description and modeling, supervised practice, pre-correction for problematic settings and students, and behavior-descriptive praise of expected behavior).

The fourth phase involves the development of procedures for responding to problem behavior, including designating behaviors as minor infractions, serious violations, or illegal behavior. Responses to minor

Table 4. Features of effective discipline policies

- Presence of strong building leadership.
- Commitment on the part of school staff.
- Guidelines for administrator (versus teacher/staff) management of problem behavior.
- Staff development and training.
- Data management and evaluation.
- Structures for periodic policy evaluation and revision.
- Clear communication of rules and expectations.
- Willingness to act immediately to deliver consequences.
- Monitoring of student behavior as a group.
- Routine recognition of positive behavior.

Source. Gettinger (1988); Hawkins and Lam (1987); Mayer (1995); Walker et al. (1995).

infractions, usually managed by individual staff, include removal of attention, redirection, prompts and reinforcement, warnings involving choice, loss of privileges, use of additional resources in the school (administrators, specialists, assistance team), and documentation of the problem and intervention attempts. When minor infractions persist despite the actions of individual staff, Walker et al. recommend that a problem-solving meeting be convened so that a formal intervention plan can be developed.

The zero tolerance position adopted by many schools in the wake of incidents of school violence in recent years is a controversial response to serious rule violations. The removal of students from school often exacerbates problem behavior, since excluded students are deprived of exposure to positive influences and learning opportunities, and are more likely to subscribe to norms of antisocial, non-normative conduct (Walker et al., 1996). Arguments favoring intensive intervention while retaining students in school are especially compelling in light of research showing that 80% of all crimes are committed by high school dropouts (Walker et al., 1995).

The fifth and final phase in planning a school-wide discipline policy involves the development of procedures for keeping records related to policy implementation, and for disseminating the plan to every member of the school community (i.e., students, parents, teachers, staff, community representatives). In summary, discipline policies that employ proactive approaches emphasizing problem solving, in contrast to policies that rely primarily on reactive, punitive procedures, serve as a critical component of an effective SCP program.

Promote Caring and Stable Interpersonal Relationships Between Students and Adults

Research has demonstrated relationships between the quality of student-teacher relationships and variables contributing to school success, such as academic motivation and attitudes toward school (Anderman & Maehr, 1994; Eccles, Wigfield, Midgley, Redman, MacIver, & Feldlaufer, 1993). A caring relationship with one or more adults has been cited as a powerful protective factor for children at risk for a variety of problematic social behaviors, including substance abuse and school dropout (Doll & Lyon, 1998). A program of research conducted by Eccles and her colleagues has identified a trend of increased impersonality and fewer opportunities for sustained contact between students and teachers as students proceed through their school careers. As students reach the middle and secondary school years, social networks are likely to be disrupted as a consequence of greater numbers of students, larger class sizes, and increases in between-classroom ability grouping. Coupled with increasingly greater emphasis on teacher control and discipline and less attention to the behavior and needs of individual students, these trends fail to support—and, in fact, mitigate against—stable, caring relationships between students and their teachers.

There are several methods for improving the stability of relationships as part of a school's SCP efforts. Felner, Ginter, and Primavera (1982) described a plan where the role of homeroom teachers was redefined to allow frequent, sustained contact between students and teachers, replacing the brief, unidirectional, and impersonal communication characteristic of typical homeroom periods. Similarly, grouping students into teams or "houses," sometimes known as schools within schools or small learning communities, provides opportunities for overlap and consistency in teacher and peer contacts over the course of the school day. Mentoring strategies, which pair adult staff with students for advising, academic and behavioral monitoring, and participation in school activities, represent another promising avenue for increasing the frequency of interaction and enhancing the quality of adult-student relationships. The practice of pairing of children with adults is a major feature of the Primary Mental Health Project (PMHP) (Cowen et al., 1996). PMHP assigns "child associates," selected on the basis of their capacity for warmth and empathy, to provide direct, ongoing support services to young children at risk for school adjustment problems. The Child Development Project (Battistich, Watson, Solomon, Schaps, & Solomon, 1991) is a promising approach to school reform that views schools as caring communities. Its components include cooperative learning activities, learning experiences providing opportunities for self-direction and influence over classroom activities, teaching and modeling of prosocial values in daily interactions, disciplinary procedures by using democratic procedures in context of "classroom communities," home-school cooperation, and service activities.

MODIFY INSTRUCTIONAL PRACTICES TO INCREASE ACTIVE ENGAGEMENT IN LEARNING

The development of academic competence is a primary goal of schools, and serves as a benchmark against which the value of innovative programs is often measured. Some have argued that school-based SCP activities serve only to divert educators' attention from this goal, and recommend the elimination of SCP programs in favor of a strong, back to basics academic emphasis. In recent years, however, advocates for school-based SCP programs have pointed to the optimization of academic competence as a major objective of SCP efforts. In Project Achieve—a school-wide approach to addressing the needs of at-risk children—empirically validated components of successful academic intervention (such as curriculum-based assessment and training teachers in effective instructional methods) are emphasized along with social skills training and school climate interventions (Knoff & Batsche, 1995). In an extensive review of the literature, Masten and Coatsworth (1998) cite academic achievement as a key component of competence during the school years, while Kauffman and Burbach (1997) argue that effective instruction is "the first defense against school violence and disruption" (p. 324).

Effective instructional methods lead to students' active engagement in the learning process, whether in the form of silent reading, discussion, responding to questions, or reciting math facts. Active engagement in learning has been established as a powerful predictor of academic achievement, and can be accomplished through the provision of frequent opportunities for students to respond during instructional activities (Lentz, Allen, & Ehrhardt, 1996). Thus, SCP in a classroom might include the use of peer-assisted learning, where the probability of student responding is increased due to the "demand" characteristics of the peer-to-peer condition. Other elements of effective instruction include positive contingencies for accurate performance, immediate feedback and error correction, frequent and direct measurement of academic skill (curriculum-based assessment) to monitor progress, and aspects of the teaching process such as pacing and appropriate use of modeling, prompting, and fading procedures (Lentz, Allen, & Ehrhardt, 1996). These methods are effective both for class-wide instructional purposes and as the basis for planning interventions for students who have been identified as underachieving or mildly disabled learners. School psychologists who have expanded their role to include consultation for intervention planning will find ample opportunities for involvement in this aspect of a school's SCP program, whether through participation in curriculum-based assessment activities, as a source of information and training for teachers and other instructional personnel, or as a member of teams addressing specific academic needs.

Students' attitudes toward work play a powerful role in achieving academic success, and shape their view of themselves as competent and productive members of society (Maehr & Midgley, 1991). These attitudes are undoubtedly influenced by the nature of the work they are given to do, and the manner in which it is presented. If academic assignments consist largely of work that is not matched to students' instructional levels, or if tasks are dreary and repetitive, then active engagement in learning is unlikely to occur.

Research indicates that students' academic motivation declines over time, a finding partly attributable to changes in teaching practices from the elementary grades to middle and secondary levels (Eccles et al., 1993). Many classrooms are characterized by "ability-focused" goals that emphasize judgments about students based on their ability to achieve success and outperform peers regardless of the nature of tasks, in contrast to "task-focused" goals that promote the accomplishment of challenging tasks and the attainment of understanding, insight, or skill. Research demonstrates that a task-focused classroom environment exerts a positive influence on the motivation of students, especially those considered to be at risk for academic failure (Maehr & Midgley, 1991). Classroom practices found to contribute to a task focus include (a) the availability of choices and opportunities for decision making, (b) grouping on the basis of interests and needs rather than on the basis of ability, (c) evaluation practices that define success in terms of effort and improvement, and (d) opportunities for peer interaction and cooperation.

Task-oriented environments also eschew the practice of providing rewards for school attendance, grades, or achievement. Wonderly (1991) asserts that the unnecessary use of rewards undermines intrinsic motivation by focusing attention on the reward that results from task completion, rather than on the sense of satisfaction and enjoyment available in the work itself. Whatever role they play in influencing motivation, incentives should be used with caution and in accordance with best practices as defined in the applied behavior analytic literature. Although the use of programmed incentives is a topic of continuing debate, social expectations often require individuals to perform in the absence of an immediately apparent reward, suggesting that the promotion of intrinsic motivation ought to be an important component of SCP programs.

OFFER FREQUENT OPPORTUNITIES FOR STUDENTS TO LEARN AND DEMONSTRATE SOCIALLY RESPONSIBLE BEHAVIOR

Wigginton (1994) issued a powerful indictment of schools when, as a former teacher serving time in prison, he described the striking parallel between schools and prisons: "In some ways, life inside prison mimics that in the public schools. In both places, the way the institution responds to the individual's desire to seek meaning in life makes all the difference" (p. 64). Wigginton goes on to describe the typical school experience in the form of restricted and monitored physical movement; rules and routines devised, and decisions made, with no student input; and the threat of punishment as a primary means for behavior control. He correctly points out that the hunger to achieve a worthwhile goal can (and will) be fulfilled through socially responsible pursuits, or through antisocial pursuits such as gang membership and delinquent activity. If the best way for students to learn responsibility is for them to be given responsibility, then it appears that typical school practice (which reserves the assignment of responsibility to students already deemed responsible) fails to teach this important quality to those most in need of it.

Social responsibility is revealed in a number of attitudes and behaviors, including a sense of belonging to prosocial peer groups and institutions, endorsement of conventional norms for behavior, avoidance of peers and adults engaged in antisocial behavior, skill in self-regulation (self-discipline), and a willingness to engage in problem solving to obtain desired outcomes. The development of social responsibility is closely related to issues of classroom and school climate. In 1986, Denise Gottfredson reported the results of a study where changes in factors related to school climate (i.e., institutional response to rule violations, availability of teacher support, promotion of prosocial behavior, and recognition of positive, responsible behavior) led to decreases in student misconduct and an enhanced sense of belonging among students. Table 5 summarizes a number of school practices that promote social responsibility, including (a) instruction in self-management strategies as interventions for impulsive or inappropriate behavior, (b) active teaching of social norms and expectations for behavior, (c) promoting group accountability for the behavior of individual members, (d) encouraging student leadership, (e) providing choices in instructional matters, and (f) creating opportunities for prosocial peer interactions and meaningful decision making (Wentzel, 1991; Maehr & Midgley, 1991).

Classroom meetings are powerful devices for involving children in problem solving, addressing class-wide concerns or needs, and fostering a climate of responsibility and mutual respect. A model for class meetings has been described by Nelsen, Lott, and Glenn (1993), and this model promotes positive interaction among peers (e.g., compliment-giving and receiving), emphasizes the importance of accepting responsibility for one's actions (e.g., compliance with agreed-upon consequences for rule violations), and teaches students a respectful procedure for setting standards for behavior and resolving interpersonal differences. The author has observed school psychologists providing training to teachers in the form of modeling, guided practice, and feedback about their performance as a facilitator of classroom meetings.

Table 5. School practices that promote social responsibility

- Instruction in self-management strategies as interventions for impulsive or inappropriate behavior.
- Active teaching of social norms and expectations for behavior.
- Promoting group accountability for the behavior of individual members.
- Encouraging student leadership.
- Providing choices in instructional matters.
- Creating opportunities for prosocial peer interaction and meaningful decision making.

Source. Maehr and Midgley (1991); Wentzel (1991).

The EQUIP model, developed by Gibbs, Potter, and Goldstein (1995), serves as an example of an intervention that incorporates the dimension of social responsibility in efforts to address problematic behavior. EQUIP offers skill training and practice within the context of a supportive, prosocial peer group. Because group meetings are structured so that participants (in groups of seven to nine students) must use their newly learned problem-solving skills to help others solve personal problems, learning occurs within a motivational context driven by the desire to contribute to others. A similar model has been employed on a pilot basis with at-risk youth, who are invited to participate in student-led groups that also include prosocial peers. Groups plan and implement a service project, learning specific social skills as the need for such skills arises (McNamara, 2000).

SUPPORT THE ROLE OF FAMILIES IN PROMOTING SOCIAL COMPETENCE

Although it may not be possible for school personnel to directly intervene on stressors (e.g., poverty, unemployment) that exacerbate conditions associated with social competence deficiencies (e.g., family instability and ineffective parenting), some forms of support are within schools' ability to provide. The Parent Program component of the School Development Program developed at Yale University (Haynes, Comer, & Hamilton-Lee, 1989) employs several levels of parent involvement to achieve school improvement goals and encourage parent endorsement of educational goals. Parents become involved in the life of the school as participants in social-recreational events, providers of service in daily school tasks, such as cafeteria and playground supervision and material preparation, and as members of school governance committees. Heller and Fantuzzo (1993) found that specific, neutral, and regularly provided information to parents about children's school attendance, homework, and behavior enhances parental monitoring of behavior, and increases their support for children's active engagement in learning and school activities. In some instances, more intensive service to families is required, and may include training in appropriate child behavior management techniques.

The Homebase parent training module of the First Step program (Golly et al., 1998) includes six in-home lessons and regular check-ins to discuss progress in skills taught in the previous lesson. Lessons seek to improve children's performance in following rules, cooperating, listening, and getting along with peers. Homebase also offers group meetings for parents upon conclusion of the six-week training during which implementation issues can be discussed. The services of community-based agencies are also incorporated in the First Step program, affording an additional level of intervention for at-risk children and their families.

The Adolescent Transitions Program (ATP) (Dishion, Andrews, Kavanagh, & Soberman, 1996) includes a strong parent focus where training activities address three key family management skills: prosocial fostering (monitoring and supporting positive behavior at school), limit setting, and problem solving. Activities are conducted across 12 group sessions, augmented by four individual meetings with each participating family addressing specific change-related concerns. The program was found to be effective in engaging parents, improving parent-child relations, and improving student behavior.

EVALUATE THE IMPACT AND SUCCESS OF PROGRAM ACTIVITIES

To ensure accountability and to demonstrate student-specific outcomes, evaluation of SCP programs and their components is essential. A review of the literature from 1966 through 1993 yielded only seven studies examining the generalization effects of commercially available social skills curricula (DuPaul & Eckert, 1994), reflecting a troubling tendency to neglect SCP program evaluation. Even those SCP program elements found to be effective have not necessarily been adopted for widespread use, underscoring the need for valid and reliable evaluation procedures whose results inform decisions about program adoption (Miller, 1999). Walker et al. (1998) state the case for the need to evaluate SCP programs by using methods that can examine socially valid outcomes (i.e., answers to questions such as, "How are you going about creating a sense of discipline in schools that are chaotic and are ruled by disruptive youths and in which teachers are afraid of students?") rather than the "details" of positive gains on social skills rating measures or reports of self-esteem.

The success of social skills training (an important component of school-based SCP programs) is generally evaluated through the use of sociometric measures (peer ratings), behavior and overall competency ratings provided by parents and teachers, direct observation of performance in natural settings, and inspection of products reflecting degrees of socially competent performance (e.g., record of disciplinary referrals). Similarly, the overall impact of SCP programs can be evaluated by examining progress toward academic goals at the classroom or school levels by using curriculum-based assessment, and by obtaining an index of school climate through measures such as the Effective Schools Battery, which solicits student and teacher ratings of climate factors such as morale, student influence, race relations, clarity and fairness of rules, respect for students, planning and action, and smooth administration (Gottfredson, 1985). The School Climate Survey (SCS), an instrument administered in the School Development Program to elementary and secondary school staff and parents, can be obtained from Christine Emmons, Ph.D., School Development Program, 55 College Street, New Haven CT 06510. The Learning Environment Inventory (Walberg & Greenberg, 1997), a rating scale administered to students, is recommended for use by teachers who wish to assess the climate of middle and secondary school classrooms.'

SUMMARY

Schools influence the development of social competence through an explicit curriculum (e.g., a published social skills training program adopted for use at the primary grades; conflict mediation training for middle school students) and through an implicit curriculum. School psychologists and other educators who are involved in planning for social competence promotion must attend to an array of factors comprising the implicit SCP curriculum, such as schoolwide discipline policies, instructional practices, interpersonal interactions, and responses to the need for individualized intervention for students' academic and social problems.

Elements of effective SCP programs are present across the school-wide, specific setting, classroom, and individual student systems, and include

1. A clearly stated mission to which every member of the school community subscribes.
2. Standards for expected behavior and consistent application of enforcement methods.
3. Commitment to early identification and intervention for children at risk for antisocial behavior and skill deficiencies.
4. Pursuit of home-school linkages focusing on the improvement of parenting skills and support for prosocial behavior.
5. Use of empirically validated instructional practices, including strategies for promoting work as positive and intrinsically rewarding.
6. Opportunities for students to practice socially responsible behavior.

The information and suggestions discussed in this chapter address a broad range of program elements and methods. The reader may be overwhelmed at the magnitude of the challenges facing school-based SCP programs, which include adequacy of resources (funding, personnel, materials) and the likelihood of resistance or reluctance on the part of school personnel to adopt a comprehensive view of SCP programming. Although discussion of these critical issues is beyond the scope of this chapter, school psychologists must approach the planning process with an awareness of their importance and impact. The comprehensive conceptualization of SCP presented in this chapter is intended to inspire creative thinking about empirically supported initiatives that hold promise for developing socially competent youth, rather than as a mandate for the inclusion of particular program elements. The effectiveness of school-based SCP programs depends in large measure on the extent to which program values and practices are integrated into the daily life and routines of the school, rather than on the presence of elaborate or costly program elements.

ANNOTATED BIBLIOGRAPHY

Campbell, P., & Siperstein, G. N. (1994). *Improving social competence: A resource for elementary school teachers*. Boston: Allyn & Bacon.
The authors of this text designed it as a practical resource for general education teachers, but its wealth of practical strategies makes it a valuable addition to the library of school psychologists. Chapters address classroom and student variables that are amenable to intervention, such as the use of classroom rules, management of transitions, cooperative learning methods, and social skill development. Detailed descriptions of modeling and coaching activities are provided, along with resources for teacher-administered assessments.

Elias, M. J., Zins, J. E., Weissberg. R. P., Frey, K. S., Greenberg, M. T., Haynes, N. M., Kessler, R., Schwab-Stone, M. E., & Shriver, T. P. (1997). *Promoting social and emotional learning: Guidelines for educators*. Alexandria, VA: Association for Supervision and Curriculum Development.
School psychologists interested in learning more about a comprehensive approach to SCP in schools will find this a valuable resource. The authors describe how social and emotional learning can be incorporated in the curriculum and reflected in school climate, and recommend specific strategies for accomplishing these objectives. In addition to providing a curriculum "scope and sequence" by grade levels, the text identifies key skills (self-regulation, perspective-taking, and relationship skills) that should be embedded in SCP programs, and addresses issues related to organizational change. Finally, the authors provide descriptions and contact information for 23 empirically supported SCP programs, including the Child Development Project; Promoting Alternative Thinking Strategies (PATHS); the School Development Program, Second Step Violence Prevention; and I Can Problem Solve, a curriculum designed for young children.

Walker, H. M., Colvin, G., & Ramsey, E. (1995). *Antisocial behavior in school: Strategies and best practices*. Pacific Grove, CA: Brooks-Cole.
This text goes beyond an emphasis on antisocial behavior to provide a comprehensive, in-depth description of a range of issues and activities related to school-based

social competence promotion programs, including school-wide discipline plans, instructional interventions, and proactive strategies for managing disruptive and socially deficient behavior.

NETWORKS

The National Mental Health and Education Center for Children and Families has been created by the National Association of School Psychologists as "an information and action network" that provides leadership and information for schools to address problems of school failure, classroom disruptions, and youth violence. This resource can be accessed via the internet at http://www.naspweb.org/center.html.

The Collaborative for the Advancement of Social and Emotional Competence (CASEL) is a network supporting educational and mental health initiatives in social competence promotion. Its purposes are to promote standards and evaluation practices for SCP programs, to compile and disseminate information about model programs and practices, to increase opportunities for educators to receive training in SCP practices, and to educate public policymakers and government administrators about effective SCP programs. CASEL's mailing address is Department of Psychology, The University of Illinois at Chicago, 1107 W. Harrison St., Chicago, IL 60607-7037. It also can be accessed via the internet at http://www.cfapress.org.casel/casel.html

59 Best Practices in Promoting a Positive School Climate

Camilla A. Lehr
Sandra L. Christenson
University of Minnesota

OVERVIEW

"A school's climate is its atmosphere for learning. It includes the feelings people have about the school and whether it is a place where learning can occur. A positive climate makes a school a place where both staff and students want to spend a substantial portion of their time; it is a good place to be" (Howard, Howell, & Brainard, 1987, p. 5).

"School climate is a relatively enduring quality of the entire school that is experienced by members, describes their collective perceptions of routine behavior, and affects their attitudes and behavior in the school" (Hoy & Miskel as cited in Hoy & Feldman, 1999, p.85).

"In general, school climate refers to the quality and consistency of interpersonal interactions within the school community that influence children's cognitive, social, and psychological development. These interactions include those among staff, between staff and students, among students, and between home and school" (Haynes, Emmons, & Ben-Avie, 1997, p. 322).

Definitions of school climate are many and varied. Researchers who have studied school climate have defined it in different ways. Educators who work to improve school climate describe it in a variety of ways, and when asked about school climate, students and parents tend to focus on different aspects. Nevertheless, students, parents, educators, and researchers sense a school's climate upon entering the building. During the initial contact with a school, first impressions occur, and one comes away with a snapshot of a school and its climate. Repeated encounters with the school and its inhabitants, extended associations with the school, or more active involvement in the day-to-day operations of the school result in the creation of a sharper image of the school's climate. A clear sense of whether the school provides a warm, friendly, and safe learning environment is developed. Questions about whether there is order and discipline, as well as high expectations for learning can be answered. Quality of leadership, degree of collaborative decision making, and respectful interpersonal relations (between students, staff, and parents) can be ascertained. There is strong evidence indicating school climate is indeed a tangible quality with implications for student learning and development.

A review of the literature suggests a variety of components comprise the construct of school climate. Although there is significant overlap across the components, each is also quite distinct. Anderson (1982) conducted a comprehensive review of research studies in the area of school climate and provided a summary of the variables that appeared to be tied to climate and/or positive student outcomes. Her categories and associated variables are listed below:

1. Ecology variables: Physical/material variables in the school that are external to participants, such as building characteristics (e.g., cleanliness, lighting, equipment), school size, and classroom size.

2. Milieu variables: Variables that represent characteristics of individuals in the school, such as teacher characteristics (number of years teaching), satisfaction, teacher morale, student body characteristics (demographic information), and student morale.

3. Social system variables: Variables that concern patterns or rules (formal and informal) of operating and interacting in the school, such as administrative organization, instructional programming, ability grouping, administrator-teacher rapport, teacher shared decision making, communication, teacher-student relationships, student shared decision making, opportunity for student participation, teacher-teacher relationships, and community school relationships.

4. Culture variables: Variables that reflect norms, belief systems, and values of various groups within the school such as teacher commitment, peer norms, cooperative emphasis, expectations, degree of consistency, consensus, and clear goals.

More recently, a review of the literature conducted by staff at the Yale Child Study Center yielded a comprehensive list of 14 components that characterized school climate (Haynes et al., 1997). The important ingredients of a healthy supportive school climate are listed in Table 1.

Most lists of school climate components have significant overlap, and components generally apply to all students. A review of 33 empirical studies of effective schooling for English Language Learners found that schools characterized by a positive school climate emphasized high expectations for students' academic achievement, along with promoting student/family involvement in the operation and activities of the school and recognizing/valuing the linguistic and cultural background of the students and their families (August & Hakuta, 1997).

Table 1. **Ingredients of a healthy supportive school climate**

Component	*Definition*
• Achievement motivation	The extent to which students at the school believe they can learn and are willing to learn
• Collaborative decision making	The involvement of parents, students, and staff in the decisions affecting the school
• Equity and fairness	The equal treatment of students regardless of ethnicity and gender
• General school climate	The quality of interactions, feelings of trust, and respect that exist within the school community
• Order and discipline	Appropriateness of student behavior in the school setting
• Parent involvement	Frequency of parent participation in school activities
• School-community relations	The support and involvement of the community in the life of the school
• Staff dedication to student learning	The effort of teachers to get students to learn
• Staff expectations	The expectations of staff members that students will do well academically and will lead a successful life
• Leadership	The principal's role in guiding the direction of the school and in creating a positive climate
• School building	The appearance of the school building
• Sharing of resources	Equal student opportunity to participate in school activities, materials, and equipment
• Caring and sensitivity	The extent to which the principal shows consideration for the students, parents, and school staff and cares about their needs
• Student interpersonal relations	The level of caring, respect, and trust that exists among students in the school
• Student-teacher relations	The level of caring, respect, and trust that exists between students and teachers in the school

What are the Historical Roots of the Study of School Climate?

In her review of the history of school climate research, Anderson (1982) reported that school climate research (theory, instrumentation, and methodology) has been strongly influenced by earlier work on organizational climate in both business and university settings. In the 1950s business researchers were studying situational characteristics impacting individual behavior within organizations. Instruments were developed to assess the organizational environment, and findings were used to help design programs and strategies to improve morale, productivity, and retain employees. Instruments designed to systematically measure college environments assessed various student and school characteristics as well as student perceptions of environmental pressures exerted by a school (academic press) in relation to student performance.

Another chapter in the history of school climate began in the 1960s with an increased emphasis on the study and measurement of classroom climate. Defining, measuring, and promoting a positive climate in classrooms focused more on examining characteristics such as teacher-student relationships in the classroom, the extent to which classrooms could be characterized as individualized to meet student needs, opportunities for student participation, and degree of shared control. In general, the measurement of classroom climate involved soliciting feedback from students about the classroom environment, instructional practices, and the teacher's role. Several instruments have been developed to measure perceptions of classroom climate. On the basis of the information gathered, teachers can reflect on and modify their teaching practices and instruction. For more information the reader is referred to the work of Fraser (1986) and Burden and Fraser (1993). Whereas *classroom* climate is limited to unique features of the climate within a classroom, *school* climate encompasses the psychosocial aspects of the whole school.

Why Should School Psychologists Be Concerned With School Climate?

A POSITIVE SCHOOL CLIMATE IS AN INTEGRAL COMPONENT OF AN EFFECTIVE SCHOOL

School climate is consistently identified as a variable that is a characteristic of effective schools and one that is positively associated with academic effectiveness (Stevens & Sanchez, 1999). For many years, research has been conducted identifying factors that contribute to effective schools. In an extensive review of the research, eight factors characterizing effective schools were identified including leadership, school climate, teacher/student relations, curriculum instruction, resources and finance, physical environment, evaluation, and parent/community involvement (Borger, 1985). Research conducted by Teddlie and Stringfield (1993) across nearly 10 years confirmed several original findings of the effective schools literature including the importance of principal leadership and correlates of effectiveness including clear academic mission and focus, orderly environment, high academic engaged time-on-task, and frequent monitoring of student progress. Purkey & Smith (1983) argued that "an academically effective school is distinguished by its culture: a structure, process and climate of values and norms that channel staff and students in the direction of successful teaching and learning" (p. 68). Psychologists who work in the schools are charged to promote characteristics that comprise effective schools. The mission of the National Association of School Psychologists is "to promote educationally and psychologically healthy environments for all children and youth...." School psychologists can play an active role in creating a positive school climate, one indicator of an effective school.

THE NATURE OF THE SCHOOL ENVIRONMENT HAS BEEN SHOWN TO HAVE A STRONG INFLUENCE ON THE WAY STUDENTS DEVELOP AND LEARN

Many studies have documented the association of school climate with improved student outcomes. For example, it is more likely that students will have higher achievement, more positive self concepts, improved behavior, and higher aspirations when the climate of the school is positive (Hoy & Hannum, 1997; Kuperminc, Leadbeater, Emmons, & Blatt, 1997; Rumberger, 1995). In some cases, the link between school climate and student outcomes is relatively direct. In other cases, school climate may have a more indirect effect. For example, a favorable climate may promote a positive sense of belonging, participation in school tasks and activities, and attendance. Current research suggests these factors are more directly linked to school dropout than perceptions of school climate (Finn, 1993; Goodenow, 1993).

SCHOOL CLIMATE IS AN ALTERABLE VARIABLE THAT CAN BE IMPACTED TO AFFECT VARIOUS OUTCOMES

The opportunity to promote a positive school climate is especially encouraging in light of the many unalterable status variables associated with risk of school failure that educators are faced with on a daily basis. Although school psychologists cannot change a student's socioeconomic standing, genetic predisposition to mental illness, or ability level, we can impact the learning environment in ways that can improve student chances for a successful school experience. Furthermore, instruments are available to assess student, staff, parent, and community perceptions of school climate to help stakeholders determine areas of strength and need. From this feedback, responsive interventions can be shaped, developed, and implemented to affect real change.

IMPROVING SCHOOL CLIMATE IS A PREVENTATIVE APPROACH RATHER THAN REACTIVE OR REMEDIAL

The power of an existing positive school climate may lie in the degree to which it is an effective preventive approach. It is a prerequisite condition that facilitates a successful work or learning experience for individuals in the school setting. When high expectations are in place, order and discipline are clear, rules are consistent and fair, caring and sensitivity characterize relationships between staff and students, and reciprocal exchanges of communication with parents occur, the probability that student achievement will improve and disruptive behavior will decline increases. In schools with positive school climate, suspension rates are lower, attendance rates are higher, and students and parents have higher levels of satisfaction (Griffith, 1997; Haynes, Emmons, Ben-Avie, & Comer, 1996).

SCHOOL PSYCHOLOGISTS ARE CHALLENGED TO BE ACTIVE IN PROMOTING SYSTEMS CHANGE

Blueprint II (Ysseldyke et al.,1997) suggests that school psychologists should be leaders "in developing schools as safe, caring, and inviting places where there is a sense of community." And one of the 10 domains outlined for training and practice of school psychologists is "School Structure, Organization, and Climate." This emphasis on attending to the social context surrounding students is receiving increasing emphasis. For example, Doll (1999) calls for sweeping changes in the purpose, design, and delivery of school mental health services to children, their families, and the school that they attend. Doll and Lyon (as cited in Doll, 1999, p. 1) concluded "resilience to adversity depends as much on the characteristics of the important contexts in which children develop (e.g. family, school, community) as on the characteristics of the children, themselves." School psychologists are challenged to become active change agents initiating, supporting, and evaluating efforts to improve school climate.

BASIC CONSIDERATIONS

Theoretical Models Explaining School Climate

Over the years, several models of school climate have emerged to explain this multidimensional construct. A brief summary of two models helps to provide a better understanding of school climate and a foundation from which to promote positive school environments.

Stockard & Mayberry (1992) proposed a theoretical framework to examine the social and psychological characteristics of schools. The authors argued that the social psychological nature of schools comprising a school's climate can be organized into two broad areas: social order and social action. Social order consists of the norms and values, environmental climate, and organizational structure of the school. Social action includes the day-to-day interactions among members and includes the quality of communication and the planning and implementation of activities within the school. Each of these dimensions has an expressive and an instrumental component. Instrumental actions clarify and maintain goals and provide the necessary material support to accomplish the objectives of the organization (i.e., high academic achievement). Expressive actions promote positive feelings, motivation, and cohesion among school members. When cross-referenced, four components result. These are illustrated in Figure 1.

This model links affective, cultural aspects of school climate with more structural components of the organization including task accomplishment and achievement. Use of the model can guide the development of questions to self-evaluate the relative

Figure 1. A model of school climate in elementary schools

	Social order (School Structure)	Social action (Interactions/Relationships)
Instrumental support (Focus on achievement/task accomplishment)	Social order instrumental e.g., My school is neat and clean; there is enough space.	Social action instrumental e.g., My teachers help me think about new ways to do things; teachers let me know how I am doing.
Expressive support (Focus on promoting positive feelings)	Social order expressive e.g., My principal treats students fairly; there is an adult I can go to when I have problems with my friends.	Social action expressive e.g., I like my class; my classmates are friendly.

Source: Stockard & Mayberry (1992).

emphasis and effects of the structures, relationships, and supports that are in place. For example, do the interactions between staff, students, and parents support a high level of academic performance? Does the school structure promote positive feelings for students and staff? Does interaction between school members promote positive feelings? Is there a balance between the four components or is one emphasized more than the others?

Hoy, Tartar, and Kottkamp (1991) proposed another model, summarized in Table 2, characterizing a school's climate in terms of its health. They conceptualized healthy schools as consisting of three levels (technical, managerial, and institutional) working in harmony to address both instrumental and expressive needs and to achieve the mission or goals of the school. The technical level (morale, cohesiveness, and academic emphasis) is concerned with the teaching-learning process; the managerial level (principal influence, consideration, initiating structure and resource allocation) encompasses the internal administration of the school; and the institutional level (integrity) connects the school with its surrounding environment. When these levels are working harmoniously, the authors speculate that the instrumental goals (reaching high levels of achievement, intellectual growth) as well as expressive goals (emotional growth, high levels of trust and motivation) will be met.

From this list of components, it becomes clear that school climate is best understood as a multidimensional construct. Furthermore, all parts are necessary in order for a profile of a healthy school to be created.

Research on School Climate and Associated Outcomes

Studies have found school climate to be linked with a variety of outcomes, including student achievement, absenteeism, self-concept, behavior, and rate of suspension (Anderson, 1982; Haynes et al., 1997). In reviewing research on school climate, the reader is cautioned to be aware of the variety of attributes used to represent the construct of school climate. These attributes range from structural characteristics, such as school size, to data reflecting conditions of the school, such as the number of disciplinary problems, to student, teacher, or parent perceptions of the degree to which interactions are respectful. Despite the variety of ways that school climate is operationalized in the research, evidence has accumulated to suggest that the nature of the environment does indeed play an important role in student outcomes.

Table 2. Dimensions of organizational health

Technical level

- *Morale* is a collective sense of friendliness, openness, enthusiasm, and trust among faculty members. Teachers like each other, like their jobs, and help each other. They are proud of their school and feel a sense of accomplishment in their jobs.
- *Cohesiveness* is the extent to which the teachers and administrators form a coherent and integrated group. They identify with each other and the school.
- *Academic emphasis* is the extent to which the school is driven by a quest for academic excellence: High but achievable academic goals are set for students, the learning environment is orderly and serious, teachers believe in their students' ability to achieve, and students work hard and respect those who do well academically.

Managerial level

- *Principal influence* is the principal's ability to influence the actions of superiors.
- *Consideration* is principal behavior that is friendly, supportive, open, and collegial.
- *Initiating structure* is principal behavior that is both task and achievement oriented. Work expectations and standards of performance are clearly articulated by the principal.
- *Resource allocation* refers to a school where adequate classroom supplies and instructional materials are allocated to teachers and extra materials are readily supplied if requested.

Institutional level

- *Institutional integrity* is the school's ability to cope with its environment in a way that maintains the educational integrity of its programs.

Source: Hoy, Tartar, & Kottkamp (1991).

In a classic study, Brookover et al. (1978) found that school climate (defined primarily as academic norms and expectations of the school) contributed to the prediction of mean school achievement over and above achievement predicted by socioeconomic status and racial composition. When school climate was entered prior to SES and racial composition in multiple regression analysis, more than 72% of the variance in average school achievement was explained in a statewide random sample of 68 schools. Schools with high proportions of students from low socioeconomic backgrounds and high levels of academic achievement were characterized as having strong positive climates that fostered student self-efficacy, learning, and achievement. Brookover et al. (1978) concluded "that school composition does not necessarily determine school climate and therefore changes in school composition (changes in SES or race) in the absence of changes in climate do not guarantee changes in school level achievement" (p. 316). In their measurement of dimensions of organizational health in middle schools and academic achievement, Hoy and Hannum (1997) found school climate (as indicated by a general health index) was positively associated with student achievement in math ($r = .61$, $p < .01$), reading ($r = .58$, $p < .01$), and writing ($r = .55$, $p < .01$).

Several studies have examined the relationship between characteristics associated with school climate and truancy or dropout rates. Characteristics associated with dropout include weak adult authority, a climate of low expectations, large school size, and an absence of caring adult relationships (Wehlage & Rutter, 1986). Bryk and Thum (1989) found that 67% of the school level variance in rates of absenteeism could be explained by a variety of school level factors. Absenteeism was lower in schools with strong academic press, high student participation in academic pursuits, an orderly environment, few disciplinary problems, less internal differentiation between curriculum, and where perceived quality of teaching was high. Smaller school size contributed to engaging students at-risk, and student attendance was better in schools where adult authority and discipline policies were perceived to be fair and effective (Rumberger, 1995). By using data from the National Education Longitudinal Survey, statistical analyses revealed an increase of one standard deviation in the proportion of students who reported a fair discipline policy reduced the mean odds of dropping out by 21% ($p < .01$). Findings from these studies support the idea that internal features of schools can affect the outcomes of absenteeism and dropout for all students, and especially youth at-risk of school failure.

School climate has been associated with student behaviors and attitudes. Students' perceptions of a positive school climate are moderately correlated with a more positive attitude toward school as defined by motivation for schooling, academic self-concept, sense of control over performance, and sense of instructional mastery (Lehr & Lange, 1999). Two aspects of school climate, commitment to school, and positive feedback from teachers have been found to predict growth in students' global and academic self-esteem (Hoge, Smit, & Hanson, 1990). Boys attending middle schools who have a more positive perception of school climate tend to have fewer externalizing behaviors (e.g., aggression, delinquent behavior). Kuperminc, Leadbeater, Emmons, and Blatt (1997) found that positive perceptions of school climate were related to lower levels of externalizing problems ($r = -.47$, $p < .05$). Although this study does not allow conclusions about the direction of effects, findings suggest student perceptions of middle school climate may impact boys' behavioral and emotional adjustment.

Also, positive school climate has been associated with higher levels of parent and student satisfaction. In a study of 122 elementary schools, Griffith (1997) found parental satisfaction was best predicted by parental perceptions of a positive school climate ($p < .001$), followed by the school's empowering parents ($p < .001$) and informing parents of their child's educational progress ($p < .001$). Student satisfaction also showed a positive correlation with a more favorable perception of school climate ($r = .22$, $p < .05$). School staff who perceives a positive school climate also tended to have higher levels of job satisfaction and showed greater self-efficacy (Hoy & Woolfolk, 1993).

Findings from research examining school climate are particularly encouraging for practitioners because educators *can* effect positive change in the culture of the school if they have informed feedback from students, parents, and staff about the nature of relationships and conditions in the school. Many studies have linked a positive school climate with important student outcomes. School psychologists can share research associated with school climate and highlight its link with important student outcomes. By assessing a school's climate, educators can make informed decisions about what is working well and where change is needed.

BEST PRACTICES

Measuring School Climate

The assessment of school climate is critical to the improvement of the school learning environment. To develop a responsive action plan individualized to the needs of the school, the climate of the school must be clearly described prior to intervention. Theoretically, instruments designed to assess school climate should provide a picture of the relative health or personality of the school. This information can be gathered from multiple people (students, teachers, support staff, administrators, parents, and community members) and from perceptions of activity throughout the school. It is recommended that climate instruments are best used as "benchmarks for growth rather than hammers for change" (Freiberg, 1999, p. 5). The information that is gathered enables stakeholders within the school to highlight relative areas of strength and areas needing improvement. The information can be especially valuable for school staff to use as a means of self-reflection and self-improvement.

There are two basic kinds of climate measures: indirect and direct. Indirect measures are those where data collection does not require direct interactions with individuals. Examples include existing data sources such as student attendance, frequency of discipline referrals, suspensions, teacher rates of turnover, or student mobility rates. Indirect measures may also document physical aspects of the building, including cleanliness, maintenance, lighting, or display of student artwork or academic work. In contrast, direct measures involve gathering information from others. These kinds of measures most often include the use of climate surveys, questionnaires, interviews, or focus groups.

Direct measures of school climate are based on perceptions of others within the school setting or in the surrounding community. School climate is generally thought to be a shared perception of between groups. For example, teachers within the same school probably have a similar view of the school in terms of the general level of discipline, respect for students, level of parent involvement, or quality of leadership. Yet, it is possible that different groups within the school may have differing perceptions of the school climate. For example, we know that dropouts have a less favorable view of school climate as compared to those who persist, and students at risk attending high schools have less favorable views of school climate as compared to students not at risk (Lehr & Lange, 1999). Some may argue that these differences reflect differences between the individuals rather than the climate of the school. However, individuals involved in efforts to improve a school's climate must be cognizant of working to ensure the school is a positive place to be for *all* students.

Currently, a variety of tools designed to measure school climate are in existence. Instruments range from those that are published and have information about technical characteristics to those that have been developed informally to measure one aspect of school climate. In some cases it may make sense to design and implement an instrument based on the climate issues specific to the needs of a particular school. While locally developed instruments lack normative comparisons, and information on reliability and validity, they may provide more individualized feedback on climate factors relative to a school or district. Development of instruments to assess school climate should, nevertheless, be firmly based on theoretical constructs gathered from the relevant literature.

For the purpose of this chapter, five instruments have been selected for further description and explanation. The following criteria were considered in their selection: grounded in a theoretical framework, stated purpose for which instrument was designed, evidence of technical characteristics (reliability and validity), previous use in research and practice, number of items, ease of administration, comparable forms for various age groups or stakeholder groups, sample content, and date of publication. Each instrument has unique features and should be selected for use on the basis of user needs. In addition, these tools are easily accessible, user friendly, and are not expensive to administer. School psychologists are encouraged to share information about these instruments with colleagues, parents, or other educators who are interested in pursuing measurement of school climate using standardized measures. Information about how to obtain copies of these instruments is included at the end of this chapter.

1. Comprehensive Assessment of School Environments (CASE) (National Association of Secondary School Principals, 1986).
    - *Purpose.* Designed to measure the shared perceptions about the characteristics of an organization (school climate). The climate survey can be administered alone or with an accompanying set of satisfaction surveys to be completed by students (grade 6–12), teachers, and parents.
    - *Dimensions.* Teacher student relationships, security and maintenance, administration, student academic orientation, student behavioral values, guidance, student-peer relationships, parent and community-school relationships, instructional management, student activities.
    - *Number of Items.* 55.
    - *Levels/Age Groups.* For use with students in grades 6–12, teachers, parents, or members of the community.
    - *Technical Adequacy.* A technical manual is available containing information on validity and reliability. Dimensions were constructed after extensive exploratory and confirmatory factor analysis was conducted. Content validity is supported through the use of an expert panel in the selection and development of the items. The average internal consistency measure for scales on the Climate Survey is .81 (range of .67 to .92).
    - *Norm Group.* Norms were established based on nearly 7,900 students, 1,800 teachers, and 3,700 parents in 35 schools across the nation.

2. Effective School Battery (ESB) (Gottfredson, 1991).
    - *Purpose.* Designed to assess perceptions of students and teachers about school climate. The instrument also includes scales and items assessing characteristics of the students who attend and teachers who work in the school.

- *Dimensions.* Safety; respect for students; planning and action; fairness of rules; clarity of rules; and student influence (student version); safety, morale, planning, and action; smooth administration; resources; race relations; parent/community involvement; student influence; avoidance of grades as sanctions (teacher version).
- *Number of Items.* 31 items (student); 61 items (teacher).
- *Levels/Age Groups.* For students in grades 7–12, and secondary level teachers.
- *Technical Adequacy.* A technical manual is available containing information about reliability and validity. Estimates of internal consistency using Cronbach's alpha for the individual scales range from .70 to .90. One-year stability coefficients for the individual scales range from .62 to .84. Items and scales were developed through extensive research in the area of school climate and effective schools. In addition, correlations among the psychosocial climate scales suggest further evidence of the instrument's validity.
- *Norm Group.* Norms have been established and profiles of schools can be interpreted by examining percentile ranks. The ESB has been used with hundreds of schools. However, data about the norm sample were not included in the technical manual.

3. Organizational Health Inventory (OHI) (Hoy & Feldman, 1999).
    - *Purpose.* Designed to measure aspects of school climate via ratings of the extent to which specific behavior patterns occur in the school. The scores that are generated provide a health profile of the school.
    - *Dimensions.* Institutional integrity, initiating structure, consideration, principal influence, resource support, morale, academic emphasis, overall health index.
    - *Number of Items.* 44.
    - *Levels/Age Groups.* For use with middle school and secondary grade level teachers.
    - *Technical Adequacy.* Reliability scores (alpha coefficient) for each subtest range from .87 to .95. Construct validity for each of the scales is supported through factor analysis. In addition, each of the dimensions had high factor loadings on the general factor of school health.
    - *Norm Group.* Authors note norms were developed in an earlier study of a large, diverse sample of high schools from New Jersey.

4. School Climate Survey (Haynes et al., 1996).
    - *Purpose.* Designed to assess dimensions of school climate.
    - *Dimensions.* Fairness, order and discipline, parent involvement, sharing of resources, student interpersonal relations, student teacher relations, achievement motivation, school building, general school climate (students), achievement motivation, collaborative decision making, equity and fairness, general school climate, order and discipline, family involvement, school-community relations, staff dedication to student learning, staff expectations, leadership, school building (staff) academic focus, achievement motivation, caring and sensitivity, collaborative decision making, parent involvement, school-community relations, school building, general School climate (parents).
    - *Number of Items.* 53 items (elementary and middle school student survey); 55 items (high school student survey); 79 items (school staff survey); 55 items (parent survey).
    - *Levels/Age Groups.* Four versions of the School Climate Survey are available for use with elementary and middle school students, high school students, school staff, and parents.
    - *Technical Adequacy.* Content validity was established via the use of an expert panel. Factor analysis was used to group items measuring the same constructs. Internal consistency reliability estimates are presented for each dimension by survey. These range from .70 to .97 on all scales except parent involvement (elementary/middle school version), which is .59, and achievement motivation involvement (elementary/middle school version), which is .64.
    - *Norm Group.* National norms are available based on schools randomly selected from a national database of schools. Samples included about 6,500 elementary, 11,800 middle, and 7,200 high school students as well as 1,900 school staff and 1,800 parents.

5. School Level Environment Questionnaire (SLEQ) (Fischer & Fraser, 1991).
   - *Purpose.* Designed to assess teachers' perceptions of psychosocial dimensions of the environment of the school. In addition to a form that measures perceptions of actual or experienced learning environments, the SLEQ has another form to measure ideal or preferred perceptions of the learning environment.
   - *Dimensions.* Student support, affiliation, professional interest, staff freedom, participatory decision making, innovation, resource adequacy, work pressure.
   - *Number of Items.* 56 (seven items per subscale).
   - *Levels/Age Groups.* For use with elementary and secondary grade level teachers.
   - *Technical Adequacy.* Not available.
   - *Norm Group.* Not available.

Programs and Strategies Designed to Promote Positive School Climate

Many programs and strategies designed to foster positive school climates exist in the literature, and undoubtedly there are other important efforts that are occurring across our nation that are not documented. For this chapter, several programs and strategies illustrating the varied forms that climate improvement projects can take are described. These projects vary according to the size of the effort (e.g., comprehensive, single strategy), the targeted components for improvement, and who is primarily responsible for initiating the effort. Although these examples do not speak specifically to the role of school psychologists, it is easy to see how these programs and strategies could have been carried out with a school psychologist as a key participant in the process. All examples use a tool to measure school climate (or an aspect of it) prior to intervening, and an evaluation of the process or final results of the climate improvement effort.

LARGE-SCALE PROGRAMS WITHIN THE CONTEXT OF SCHOOL REFORM

The improvement of school climate often takes place as part of a large-scale reform effort. Perhaps the most comprehensive and widely disseminated example of a program that seeks to improve student outcomes largely through initial changes in school climate is The Yale Child Study Center School Development Program (SDP) (Comer, Haynes, Joyner, & Ben-Avie, 1996). The program is now being implemented in over 700 schools nationally and internationally and involves parents, teachers, and students in the management and coordination of all school activities. Creating a positive school climate that nurtures and sustains good psychological development and high levels of academic performance is a key feature of the model.

SDP consists of nine program elements that provide specific ways for adults to manage their relationships and plan activities to improve the climate and academic focus of their school. The nine elements include three teams, three guiding principals, and three operations. The teams include the

1. School Planning and Management Team (SPMT): Responsible for planning, coordinating, and managing the school program with input from the other two teams.

2. Student and Staff Support Team (SSST): Responsible for identifying and addressing school-level and individual student and staff concerns that affect school climate, student adjustment, and performance. This team includes individuals with expertise in child development and mental health (e.g., school psychologists, counselors, speech therapists, special education teachers, nurses) who help to identify or design programs and activities to address children's growth and development.

3. Parent Team (PT): Responsible for supporting the general mission and work of the school through parent involvement in all aspects of school life.

The three principles that guide the functioning of these teams include (a) a *no-fault* approach that requires teams to adopt a problem-solving approach to address issues, (b) a process of *consensus* that allows decisions to be made after ideas and perspectives are shared in an atmosphere of trust and mutual respect, and (c) an emphasis on *collaboration* that includes teamwork, collegiality, and shared responsibility among all team members. The SPMT is primarily responsible for the three operations including (a) the goals and activities to promote student growth for the year (Comprehensive School Plan),

(b) staff development and training, and (c) ongoing assessment and modification to document progress, identify necessary modifications, and measure outcomes.

The creation of a positive school climate is central to the work of the three teams. Effective integration and coordination of the key elements occur within the context of a positive school climate. Haynes (1998) describes the role of school climate in schools that are using the School Development Program.

> The effects of the nine SDP program elements on student performance outcomes are mediated by several essential climate dimensions, including sensitivity and caring, respect and trust, high expectations, high achievement motivation, effective leadership, strong order and discipline, a collaborative spirit, helpful and supportive teacher-student relationships, and positive student interpersonal relationships. If the SDP is implemented well, these dimensions permeate the life of the school, resulting in desirable student outcomes when coupled with effective teaching and learning strategies. An improved climate provides the context in which effective teaching and learning can take root and bear fruit.
>
> In well-functioning SDP school, there is an observable positive quality of life for students, staff, and parents. Mutual trust and positive regard characterize social interactions and students derive a sense of academic self-efficacy. In many SDP schools there is a progression of positive changes in climate, followed by positive changes in students' attitudes and behavior, followed by achievement growth (p. 7).

Goals for improving school climate are based on information gathered from climate scales developed by the Yale Child Study Center (see *School Climate Survey* instrument description). Initial assessments completed by students, staff, and parents provide baseline data that guide the design of strategies to address specific needs. Follow-up assessments help to determine whether change has occurred or whether further intervention is required.

A case study of an elementary school shows how the SDP is implemented and how school climate can be impacted (for a more detailed description see Emmons, Efimba, & Hagopian, 1998). In 1991, Norman S. Weir was described as one of the lowest achieving schools in New Jersey, characterized by student apathy and disinterest in academics, frequent fights, low staff morale, and a building that was in disrepair. The school served about 260 students in grades K–8, with a student body that was 40% African American, 40% Hispanic, 18% other nationalities, and 2% Caucasian. About 83% of the students received a free or reduced lunch over the past 4 years, and about 30% of the students received special education.

Improving the school climate was one of three main goals identified by school staff. Seven committees were formed to address designated areas related to the goals, and representatives from each committee brought issues and concerns to the SPMT through a representative committee member. One committee was designed specifically to address school climate issues. This committee (as well as each of the other committees) was responsible for developing and submitting a list of goals and objectives to improve school climate, activities to implement the objectives, and a way of evaluating when those objectives were met. Several strategies were implemented to improve the school climate. These strategies were implemented in conjunction with other activities generated by other committees to achieve the goals of improving student achievement and increasing parent involvement. Some of these strategies specific to school climate were

1. To improve caring and sensitivity as well as student teacher relations, staff viewed students as their own children and talked with them in ways that encouraged students to share their attitudes and personal issues.

2. To build student teacher relations (and promote achievement and build on student strengths), a looping strategy was incorporated so that students had the same reading teacher, math teacher, and language teacher for three years.

3. To promote achievement motivation and a strong academic press, teachers were asked to identify one or two students per class who would benefit from participating in an after-school phonics program.

4. To promote staff dedication to student learning, poverty, home environment, parent neglect, or urban location of the school were not allowed to be used as excuses for low student expectations or a low-level curriculum.

5. To improve staff expectations and sense of self-efficacy, consistent use of a no-fault approach that converts negative blaming energy to positive, problem-solving strategies was implemented.

6. To increase collaborative decision making and collegiality and feelings of inclusion and ownership, participation of each staff member on at least one committee was required.

7. To improve school building conditions, students took initiative to form a student council, and purchased new gym equipment as one of its first projects.

Efforts to make abstract ideas explicit by stating clear goals with shared contributions and shared accountability reflects and creates a positive school climate. After 5 years of implementation, the school was described as one of the highest achieving schools in the district. It became bright, clean, and well maintained. Staff members became enthusiastic about their work, and collaborated with each other in order to promote the healthy development and academic achievement of their students. Staff was also willing to engage parents as partners in the education process. Students became excited to learn, proud of their work, and volunteered to take part in activities that promoted school improvement. The authors caution that the process of school improvement and promoting positive school climate does not end once promising results have occurred. As new staff members are employed, they must receive training and become participants in the ongoing efforts. The involvement of new parents must be encouraged and nurtured. In addition, veteran staff and parents must be continually stimulated to maintain the focus on sustaining healthy psychological development and high levels of academic performance for all students. This example points to the challenge of implementing a comprehensive program, and school psychologists who are involved in these kinds of efforts must recognize the need for persistence over time in order to observe measurable impact.

PROGRAMS ADDRESSING SCHOOL CLIMATE ON A SMALLER SCALE

The improvement of school climate does not necessarily have to occur in the context of large-scale school reform. An example of promoting positive school climate on a smaller scale has been described by Andringa and Fustin (1991). Implemented in a suburban school serving students in grades K–8, this school climate project was lead by a principal and university researcher but involved the active participation of the entire faculty. A committee was formed consisting of four teachers (who had volunteered to be on the committee) and the principal. This committee served to evaluate, modify, and personalize the model of change that was proposed. In addition, the four teacher volunteers became group facilitators for the remaining 40 teachers in the school.

To begin the process of improving the school climate, each teacher was asked to identify and bring three concerns about the school's climate to the next meeting. Concerns focused on the quality of interaction between school, parents, and community; the quality of interaction between teachers and the administration; and the quality of interaction between teachers and students. The authors described a deliberate process of developing their own measurement instrument rather than using an existing instrument to assess actual concerns of the teachers. Drawing on previous tools developed to measure the discrepancy between what is perceived as the current situation (what is) and what is desired (what should be), the committee developed a 43–item instrument to assess indicators of school climate across the three major areas of concern. After staff completed the measures, four indicators showing the largest mean discrepancies were targeted for change.

According to Andringa and Fustin, an important key to the success of this climate improvement effort was the allocation of eight half days of release time over a 2–year period for collaborative planning (granted by the school board). In addition, a consensus decision-making process was used to ensure the open exchange of ideas, allowing each individual's concerns to be heard, understood, and considered before agreement was reached. Efforts initially focused on developing the collaborative problem-solving teams, and each group selected a recorder and process monitor (separate from the group facilitator). The principal and the university consultant circulated among the groups to further monitor the group process. Prior to each of the half-day meetings, the consultant met with the main committee to present and explain the agenda for the half-day meeting, as well as explain, model, and role play the process. The first three meetings included the entire faculty. Tasks consisted of defining what should be included as part of the indicators; clarification and categorization of ideas into objectives; and ranking of objectives in order of importance. Each group was then charged with developing implementation plans for each of the four identified indicators of school climate. Implementation plans included breaking the activity into steps, identifying who was responsible for the plan, and the anticipated time line for completion.

The four indicators by group are listed below with an activity designed and implemented by each group:

1. Group A Indicator: The community supports the school's teaching program.
    - *Activity.* To recognize and honor students who have achieved academic excellence, the school established criteria for identifying a student of the week, month, and year in each class. Class, school, and public recognition were provided via the newsletter, signs in school, and photographs in a display case. A recognition dinner with parents was held in May for those students with three or more grading periods on the honor roll.

2. Group B Indicator: Teachers feel that they have important input into school decisions.
    - *Activity.* To improve the transition for new teachers, veteran teachers paired themselves with new teachers. In addition, a 1-day in-service was provided and a handbook with all policies and procedures was developed and disseminated.

3. Group C Indicator: Students believe the school program is meaningful and relevant to their present and future needs.
    - *Activity.* To increase student awareness of the importance of their school work, teachers displayed students' work throughout the school, as well as in each classroom. Class activities were described in the newsletter. Positive reinforcement was provided by teachers for efforts to improve and succeed.

4. Group D Indicator: The school supports parent growth through the provision of opportunities to be involved in learning activities.
    - *Activity.* To increase parent and community awareness of school activities, students published a school newsletter and mailed one to every resident of the surrounding community (four times annually).

All activities were carried out over a 2–year period. The teachers agreed that change had occurred in addition to the stated objectives. Specifically, there was evidence of increased communication among faculty, better services for students, intercollegial interaction, and more immediate problem solving. An evaluation assessing teachers' reactions to the change process at the end of the second year revealed a clear understanding of the process and the belief that change needs were collaboratively identified. Loss of instructional time due to half–time release days, nonpayment for planning time beyond the school day, and the perception that not all faculty followed through on implementations were seen as weaknesses by the staff. Despite areas of weakness, faculty agreed to continue to determine needs and monitor implementation of objectives on an ongoing basis.

STRATEGIES ADDRESSING ELEMENTS OF SCHOOL CLIMATE

Oftentimes, rather than implementing a plan to address multiple aspects of school climate, one component of school climate is addressed. For example, educators may choose to focus on particular elements of climate such as the school's physical environment, interpersonal relationships, safety issues, or fostering greater parental or community involvement through the creation of welcoming environments. Cooperative learning strategies, programs addressing violence or bullying, in-house suspension programs that focus on incorporating a problem–solving approach, cross-grade level partnerships for children, weekly school meetings, or creating welcoming environments by decorating the school building with student artwork are examples of strategies used to promote positive school climates and learning environments. Freiberg (1998) noted that surveys of students and observations at school can help educators to identify small changes leading to significant improvements. He shared three examples of ways varying aspects of school climate can be measured and addressed.

One example describes a series of questions asking fifth and sixth graders and middle school students to identify their greatest concerns in moving from their current school to the next level. Survey results indicated top ranked concerns for students entering middle school were being sent to the principal, failure, drugs, taking tests, and giving a presentation in front of others. For students entering high school, top-ranked concerns were failure, keeping up with assignments, taking tests, and giving a presentation in front of others. Survey results were used during summer staff development workshops, where teachers and administrators developed action plans based on the information. Several strategies were developed to address student concerns. For example, introductions on the first day occurred in small groups rather than in front of the entire class, teachers helped students with study and test-taking skills, and students were given assignment/project planner books to support time-management skills. It is important to recognize feedback from students can be extremely valuable, and soliciting input helps students realize they have an opportunity to participate in shaping their educational experience.

A second example of measuring school climate is to interview students upon beginning or exiting (graduating from) a school. Questions for students graduating included (a) What do you like about your school? (b) What was your most memorable experience in high school? (c) What area would you like to have improved in your school? (d) What is one message you would like to give your teachers? Many of the students made a point of thanking teachers for making a difference in their lives. Some students made concrete suggestions about course schedules, homework, or social events in the schools. In response to the interviews (which were videotaped) teachers recognized the powerful role they played in students lives and considered modifying school tasks based on their suggestions.

The last example points to the importance of addressing seemingly small concerns as a way of enhancing school climate. The *Ambient Noise Checklist* was used to assess the noise level in the cafeteria of a Chicago school. The cafeteria was described as having excruciatingly high noise levels.

> The machines in the cafeteria were all running, an aide was using the public address system to ask Billy or Sarah to "find a seat and sit down," and the cafeteria workers seemed to be playing the 1812 Overture with the stainless steel pots and pans. Students were emptying their trays by banging them inside a metal trash can. Adults were shouting across the room asking specific students to be quiet. The students talked over this din. Few adults acted as if they were glad the students were there. The tone of the aides and other cafeteria workers was less than positive. I observed no smiles, no "good mornings," no friendly faces. When I said "good morning" to an older child, he looked at me as if I had called him a bad name. After 30 minutes in the cafeteria,'I was ready to fight" (Freiberg, 1998, p.25).

A checklist was used by the faculty and administration to identify sources of noise in the cafeteria. From this information, they developed some ideas about how to address the noise levels and proceeded to make changes, including training to help aides relate more positively to children, a teacher greeter at the front of the serving line, and use of a sponge stick to clean plates rather than banging them in the metal trash cans. In addition, students were assigned to eat at regular tables each day and were allowed to talk with any student on either side or directly across from them. Use of the speaker was discontinued, and adults walked over to children to talk with them. After several weeks, results indicated that the noise level decreased dramatically, and daily fights essentially stopped. The cafeteria became a pleasant and peaceful space within the school setting.

Guidelines for Promoting a Positive School Climate

The ingredients for promoting a positive school climate vary from school to school. Each time the recipe must be tailored to meet the needs of the students, staff, parents, and community members who are key stakeholders and participants in the creation of a healthy school environment. Yet, there are some basic guidelines that can help to facilitate a successful process and positive results. For example, Fraser (1999) suggests feedback gathered from instruments assessing school climate can be used as a basis for reflection upon, discussion of, and systematic attempts to improve school environments. He recommends the following steps that have proven effective in school climate improvement projects: (a) use of an assessment tool to gather information about perceptions of school climate, (b) compilation of data in a form that can be used as feedback about perceptions of school climate, (c) reflection and discussion of findings to help clarify implications and identify areas needing change, (d) development and implementation of an intervention, and (e) reassessment to determine whether change has occurred.

According to Freiberg (1999), the challenges of initiating a school climate improvement project can be made less overwhelming by considering five points, listed in Table 3.

Frieberg recommends initial strategies for change should begin quickly and should be visible to all students and staff. For example, at one school, staff decided to improve the faculty restrooms. They added quality paper products, assigned maintenance responsibilities across grade levels every 3 months, added air freshener, new paint, pictures, mirrors, and a bulletin board with the latest information from the school climate committee. This intervention was highly visible, and the changes enlisted the support of more faculty and staff to participate in more extensive interventions suggested by the climate committee. Another example of a quick and highly visible climate improvement strategy was initiated by a group of middle school students. These students decided that greeting students and faculty upon entering the building each morning would help improve the "friendliness" of the school.

Finally, it is especially important to consider initiating school climate improvement within the context of organizational change (Curtis & Stoller, 1995). Effecting change within schools requires changing behaviors and attitudes, as well as school organization and norms (Purkey and Smith, 1983). Change and maintenance of the change will not take place without the support and commitment of teachers who must come to "own" different or new educational ideology and techniques. A strategy of change that promotes collaborative planning, collegial work, and a school atmosphere conducive to experimentation and evaluation is critical. The most effective approach to promoting school climate sees school staff (including teachers, paraprofessionals, custodians, secretaries, etc.) as an integral part of an entire school organization engaged in development activities that take place over time. Similarly, students, parents, and community members must be included in

Table 3. Initiating school climate improvement projects: points to consider

1. *Trust your own perceptions and think about whether the school is a place where students, staff, and parents like to be.* How does the school look? How would you characterize interactions between staff and students, student and students, parents and staff? What do you feel as you enter the building? Do you sense strong leadership or high academic expectations? What evidence supports your perceptions?
2. *Consider what direct and indirect climate measures can be used to help document and create a baseline for change.* What existing data sources are available to measure school climate? Whose perceptions of school climate should be measured (students? staff? parents?). What resources are available for purchasing and analyzing surveys? Does it make sense to design and implement an instrument based on climate issues specific to needs of the school?
3. *Identify initial climate changes that can be made with a high level of visibility and within a relatively short period.* Prioritize a list of changes that will yield noticeable results. What changes do most key members of the school agree need attention? What changes can be made quickly with a minimal initial investment of time and effort?
4. *Consider what groups or individuals should be involved to encourage and create an environment for sustained school climate improvement.* Who are key players in the school? Who must be on board to help initiate and sustain this school climate improvement effort? Remember to consider membership from all major groups (student, staff, and parents). Remember to enlist the support of those who may not typically be included in school improvement efforts (community members, students considered at-risk of school failure, support staff, parents who may have been alienated in the past).
5. *Consider what long-term changes are needed to create a healthy environment for all members of the learning community.* Recognize that improving and sustaining a positive school climate is a continuous process requiring persistent and ongoing efforts. Develop a plan to maintain the changes that have been made. Develop a way of educating and including new members in the school climate improvement effort.

Source: Adapted from Frieberg (1999).

projects initiated to address school climate. Inviting a parent or student as a token representative will not suffice; to foster an investment in the project, individual contributions and participation must be welcomed, respected, and valued as part of school-wide efforts.

SUMMARY

School climate is a complex construct that has been recognized as an important component of effective schools. Definitions point to multiple dimensions including a sense of order and discipline, parental involvement, staff dedication to student learning, high expectations for academic performance and behavior, caring relationships, and respectful interactions between students, staff, parents, and community members. Today, models of school climate underscore the varied dimensions and organize the complexity of the construct. School climate is associated with a variety of student outcomes including achievement, absenteeism, self-concept, and behavior. How can school psychologists promote a positive school climate? First of all, best practice suggests that it is necessary to describe and measure school climate before developing and implementing a responsive action plan. Indirect and direct measures of school climate can be used to assess perceptions of students, staff, parents, and community members. Several tools meeting important criteria to enhance their quality (e.g., standardized, grounded in theory, evidence of technical adequacy, used in research) were reviewed in this chapter. Efforts to improve school climate have occurred within the context of national large–scale reform, or on a smaller scale at the individual school or district level. In addition, relatively simple strategies can be developed to address singular elements of school climate. Although each strategy/program will vary, there are guidelines to help ensure a successful process and positive results. It is important to conduct school climate improvement within the context of organizational change and enlist the support and active participation of key stakeholders in the school community.

School psychologists are in key positions to effect positive changes in school climate and help create schools where people like to be. Every school psychologist can begin to make these changes although they will take a variety of forms and occur at a variety of levels given job responsibilities, role definitions, and building, or district–level constraints. At a minimum, all school psychologists as professionals can participate in promoting a positive school climate by modeling desired behaviors including participating collaboratively in decision making, promoting high and achievable expectations for all students, welcoming parents as participants in the learning community, showing care and sensitivity to students as well as staff members, and interacting with others in a respectful manner. Furthermore, school psychologists must take steps to initiate awareness, interest, and programmatic changes that will improve a school's climate. As school personnel or parents become engaged in exploring and implementing change, school psychologists can offer support and bring knowledge about school climate issues (e.g., associated research, potential instruments, examples) to assist in planning. Finally, school psychologists have the training to recognize the importance of collecting data to make decisions and the skills to evaluate program effectiveness. School psychologists cannot sit back and wait for an invitation to participate; rather, school psychologists must be active catalysts for change, collaborative partners, and leaders in reform efforts directed at promoting positive school climates.

It makes sense to put efforts into promoting educationally and healthy environments for all children and youth because it has been shown to be an effective preventive approach. The words of Norris Haynes (as cited in Haynes et al., 1997, p. 322) serve to stimulate our thinking when considering the influence of school climate and student development: "poor school adjustment and school failure are often incorrectly interpreted as manifestations of cognitive ineptitude, deviant value systems, and inadequate development. The complex interpersonal interactions which occur within schools and significantly influence students adjustment and performance are not sufficiently examined". As school psychologists we are indeed challenged to address the conditions of the school environment that can help to foster academic success and healthy development for all students.

ANNOTATED BIBLIOGRAPHY

Anderson, C. S. (1982). The search for school climate: A review of the research. *Review of Educational Research, 52*(3), 368–420.

This article provides an extensive analysis of the literature on school climate, presents theories of school climate, and draws conclusions about research findings. The history of school climate is reviewed, and the article concludes with a summary of methodological issues researchers are faced with when conducting school climate studies.

Freiberg, H. J. (1999). *School climate: Measuring, improving and sustaining healthy learning environments.* London: Falmer.

This book consists of 11 chapters describing approaches to measuring school climate from multiple perspectives. The book discusses issues related to improving school climate and provides examples of many diverse kinds of climate instruments.

Haynes, N. M., Emmons, C., & Ben-Avie, M. (1997). School climate as a factor in student adjustment and achievement. *Journal of Educational and Psychological Consultation, 8*(3), 321–329.

This brief article defines dimensions of school climate and summarizes research on school climate and student outcomes. Examples of positive school climate are also provided.

Publisher/Contact Information for Select School Climate Instruments:

Comprehensive Assessment of School Environments (CASE) (NASSP, 1986).

The instrument can be ordered from the National Association of Secondary School Principals, P.O. Box 3250, Reston, Virginia 22090. Telephone: (616) 383-1961.

Effective School Battery (ESB) (Gottfredson, 1991).

The instrument, information about scoring, and the norm group can be obtained from Gottfredson Associates, Inc., 3239-B Corporate Court, Ellicott City, MD 21042. Telephone: (410) 461-5530.

Organizational Health Inventory (OHI) (Hoy & Feldman, 1999).

A copy of the SLEQ and directions for scoring are available in Hoy & Feldman (1999). APC computer scoring program for the OHI can be purchased from Arlington Writers, 2548 Onandaga Drive, Columbus, OH 43221. The program will automatically score the data and standardize the scores using the current norms.

School Climate Survey (Haynes, Emmons, Ben-Avie, & Comer, 1996).

The instrument can be ordered from Christine Emmons, School Climate Surveys Request, Yale Child Study Center, School Development Program, 55 College Street, New Haven, CT 06510. Telephone: (203) 737-4000.

School Level Environment Questionnaire (SLEQ) (Fischer & Fraser, 1991).

A copy of the SLEQ and directions for scoring is available in Fraser (1999)

60 Best Practices in Health Promotion for School Psychological Practice

Ellis P. Copeland
University of Northern Colorado

OVERVIEW

In past decades, children were susceptible to a host of deadly diseases. Advances in medical science that resulted in medications and vaccines have now largely addressed the ravages once wrought on children by the diseases of the past. Schools, along with other health and social service agencies, played a major role in eradicating infectious diseases through their involvement in immunization, screening, and educational programming. Such involvement needs to continue today yet in a radically different form.

Today's youth are exposed to multiple risk factors, and these risk factors are common antecedents of diverse disorders. Although this chapter will focus on building functional behaviors and reducing or eliminating dysfunctional behaviors in youth, the exacerbation and increase in health and behavior problems have their roots in the significant family, school, and neighborhood changes that have occurred during the past few decades (Consortium on the School-Based Promotion of Social Competence, 1994). These changes include a breakdown of the traditional family and traditional neighborhoods; a devaluing of parenting, of teachers, and of religious life; increased poverty rates among families with children; damaging television and media messages (i.e., sex, violence, and unhealthy dietary behaviors); lack of positive role models and a reduction in meaningful contact with positive adult role models; unsafe environments (often inclusive of the school environment); inadequate housing; and misplaced values where money becomes supreme amongst the unattended societal problems directly affecting the health of our youth.

The societal erosion noted above has affected the behavior of every youth in our nation. Consequently, the focus of our interventions are most closely tied to the behavioral patterns the youth may choose to adopt that too often lead to mental and/or physical disorders. Epidemiological data indicate that 15–25% of children and adolescents have mental health problems that warrant treatment and/ or place them in the "extremely vulnerable" category (Consortium on the School-Based Promotion of Social Competence, 1994). Further, the most serious and expensive health and social problems facing our country today are caused by negative behavioral patterns that were established during the childhood and adolescent years (Kolbe, Collins, & Cortese, 1997). Health problems spawned by negative behavioral patterns (smoking, unhealthy dietary behaviors, drug and alcohol abuse, intentional injury to others and self, sexual behaviors that can result in pregnancy or sexually transmitted diseases, and inadequate physical exercise) fuel unnecessary health care costs. Unattended health and social problems among our country's young people seriously erode their health status, educational achievement, and quality of life (Kolbe et al., 1997).

Still, these health problems/unhealthy behaviors are largely preventable and rigorous studies of health education in the schools have demonstrated that programming has effectively reduced the prevalence of health risk behaviors among youth. For example,

1. Planned, sequential health education resulted in a 37% reduction in the onset of smoking among seventh-grade students.

2. The prevalence of obesity was decreased by half among girls in grades 6–8 who participated in a school-based program.

3. Forty-four percent fewer students who were enrolled in a school-based life skills training program used tobacco, alcohol, and marijuana one or more times per month than those not enrolled in the program (School Health Programs, 2000).

Given these data, it appears that school health programs are becoming one of the most efficient means that the country might use to prevent the major mental and physical health problems as well as social problems that confront our nation.

The idea of delivery of health services to students in schools is an old one. Dryfoos (1994) noted that, in the 1980s, as conditions worsened for young people, school-based clinics began to pop up serendipitously around the country. The early programs were problem-focused (i.e., alcohol and drug, teen pregnancy) and were later superseded by more comprehensive models such as school-based clinics. Dryfoos' (1994) book, *Full-Service Schools: A Revolution in Health and Social Services for Children, Youth, and Families*, was about the transition from school-based clinics to full-service schools (schools in which health, mental health, social, and/or family services might be located). Today, full-service schools or "comprehensive school health education" is seen as the most effective form to promote healthy behaviors and prevent the previously outlined dysfunctional behaviors. However, without a radical change in societal values (society choosing to directly address major issues such as poverty and unsafe environments) and school mission, most of the nation's 100,000 schools will not implement a comprehensive program or a school clinic in the near future (Kolbe et al., 1997).

Although schools, by themselves, should not be expected to address the nation's most serious health and social problems, school health programs could be one of the most efficient means the nation might use to prevent major health and social problems (Kolbe et al., 1997). By reducing the incidence of mental and physical health problems that afflict young people and often continue into adulthood, school health programs should reduce the spiraling cost of health care, improve educational outcomes, and improve productivity and quality of life. Schools are widely acknowledged as the major setting in which activities should be undertaken to promote competence and prevent the development of unhealthy behaviors (Consortium on the School-Based Promotion of Social Competence, 1994). Further, from a primary and secondary prevention perspective, an economic perspective and demographic viewpoint, it appears essential that social initiatives such as health promotion be linked to schools.

Health promotion has been "broadly defined as a combination of behavioral, educational, social, spiritual, economic, and environmental efforts that support the establishment, maintenance, and enhancement of behaviors and life-styles conducive to overall emotional and physical well-being" (Zins & Wagner, 1997, p. 945). The definition is inclusive of mind, body, and spirit. Further, the definition is systemic and directly encourages the mobilization of community resources and the development of environments that will lead to healthy behavioral patterns during the child's and adolescent's formative years. What a challenge! These healthy lifestyles must be as easy to adopt as unhealthy ones and produce greater immediate and long-term rewards.

The challenge is an especially difficult one for the traditionally trained school psychologist. Although we have witnessed extraordinary progress in our improvement of public health (including mental health) through medical science, we know more today about how to treat mental illness than we know with certainty about how to prevent mental illness and promote health (Satcher, 1999). Larson (2000) notes that the various domains of psychology are more articulate about how things can go wrong than how they can go right. We have numerous research-based programs aimed at curbing at-risk behaviors such as violence and drug use, but we lack a rigorously applied psychology of how to promote positive youth development. Yet, our role becomes obvious given the well-established link between learning and health (Satcher, 1999).

Thus, health promotion will require us to be a part of a team of professionals from many fields working cooperatively with teachers, students, community members, and parents to provide comprehensive school health programs. These integrated efforts may include such disciplines as health education, nursing, physical education, nutrition (food) services, counseling, and school psychology (Zins & Wagner, 1997). The integrated approach will be better able to mobilize community resources to enhance health promotion efforts in the schools and society. Further, the comprehensive effort will reach virtually all children and youth and create an environment that builds health upon health in a more integrated manner.

BASIC CONSIDERATIONS

What We Know

We, school psychologists, know risk factors and at-risk behaviors. Smoking, early sexual intercourse, destruction of property, fighting, stealing, use of alcohol and/or drugs, and absenteeism are a few examples. Jessor, Turbin, and Costa (1998) have turned a number of obvious risk factors into health-enhancing behaviors. Noting the ill effects of not eating a healthy diet, not getting enough sleep, not engaging in regular exercise, not practicing good dental hygiene, and not wearing a seatbelt resulted in the Health-Enhancing Behavior Index. Benson (1993) further provides a list of factors that are associated with negative health outcomes.

Much of what we need to know to practice on a school health team was provided in the foundation courses of our accredited training programs. Program evaluation is taught in most of our training programs and is a key element to update, improve, and define the successful school health program. Consultation and behavioral change strategies are critical skills to enable one to effectively practice on a health team. Learning theory and developmental psychology are true assets. For example, developmental psychology is the study of the process of physical and emotional growth and competence, and is a critical sub-domain of social and emotional intelligence. Of course, a course focused on prevention would be most helpful. Still, most of us are able to "reframe" our skills to be more proactive than reactive.

What We Need to Know

Curriculum concerns that must be addressed are well defined in the Comprehensive School Health Program model developed by the School Health Programs (2000). According to the model, a comprehensive school plan provides:

1. Curriculum that addresses and integrates education about a range of categorical health issues at developmentally appropriate ages

2. Programming for grades kindergarten through twelve

3. Instruction for a prescribed amount of time at each grade level

4. Integrative activities to help young people develop the skills they need to avoid use of tobacco, dysfunctional behaviors, engaging in a sedentary lifestyle, etc.

5. Appropriate instruction from qualified teachers, health professionals, and concerned community members

A good curriculum specialist or teacher will be critical to curriculum development.

We need to perceive health promotion as its own set of assets and competencies and not the absence of disease as it is often defined by the medical model. For example, the Surgeon General (Satcher, 1999) defines mental health as

> The successful performance of mental function, resulting in productive activities, fulfilling relationships with other people, and the ability to adapt to change and cope with adversity; from early childhood until late life, mental health is the springboard of thinking and communication skills, learning, emotional growth, resilience, and self-esteem (p.vii).

Physical health is also better defined by competencies than by a lack of physical disease.

Martin Seligman, past president of the American Psychological Association, hopes to see a profound shift in the field of psychology away from pathology and toward positive psychology. In his article with Csikszentmihalyi (Seligman, & Csikszentmihalyi, 2000), they describe the foreground of this approach as prevention. Since the disease model offers little to prevent violence, depression, etc., the major strides in prevention will come largely from a perspective of building competency and not on correcting weakness. Much of the task of prevention in the next century will be on how to foster courage, future mindedness, optimism, interpersonal skill, faith, hope, work ethic, initiative, and honesty (to name several) in youth. The entire issue of the January 2000 *American Psychologist* addresses this topic.

In a related manner, Benson (1993) has identified 30 assets, referred to as protective factors, associated with positive health outcomes. Benson's acknowledged assets include caring about people, displaying assertiveness skills, motivation to achieve, positive orientation to the future, decision-making skills, involvement in church or synagogue, and acknowledgement of family support. Benson further advocates an additive view of assets that is most consistent with health goals and curriculum.

Building an Integrative Program

This section will examine some general ways to introduce and gain support for implementing a health promotion program in your school(s) or in a school district. A number of the ideas presented in the section were drawn from articles by Hightower, Johnson, and Haffey (1995) and Kelly (1995).

In any plan for change, a formal needs assessment is the best way to begin. If such an assessment is not feasible, then following one's "sense of the obvious" might be an option (Hightower et al., 1995). Such an approach involves spending considerable time in open discussion and active listening among staff to delineate a hierarchy of concerns. Once the needs are identified the homework begins. Attending workshops, visiting schools and communicating with personnel invested in a comprehensive school health program, and reading relevant journals and reports helps you to develop the expertise to better present the concept.

Before directly approaching personnel within your schools or district, a system analysis is always necessary (Hightower et al., 1995). Talking to those who know the system regarding managerial styles, communication pathways, allegiances, etc., is informative. Understanding the school board's philosophy, goals, budget for the district, procedures, etc., lets you know how the system operates. Once you know what is happening and how it happens, start at the safest point with the administrator that oversees that particular area. If the person is one of your principals, then they may be able to provide useful cues on how to proceed.

The next step is to identify school personnel that are either stakeholders and/or "customers" (people who are invested in health education) of the idea. Kelly (1995) firmly supports the idea of starting with internal support before moving to external audiences. Then, a school psychologist should obtain the input and approval of all school staff who will be involved, along with principal(s) and other supervisor input before the program is taken to the superintendent (Hightower et al., 1995). When meeting with the superintendent, be clear about what you wish to accomplish and optimistic about the level of support that the idea has achieved.

With the superintendent's blessing and approval, external audiences can be contacted. These include community agencies, parents who may be "customers," churches and synagogues, hospitals, alternative health providers, and the business community. Direct communication is far better than mass communication (i.e., newsletters), which does little to influence opinions or change behavior (Kelly, 1995). Direct communication also enables you to manage issues that may arise if the idea of health promotion is seen as too far afield by some extreme groups. Further, direct communication allows the services provided to be designed around community needs. Responding to local needs and constructing interventions to meet community needs typically results in a positive attitude from both staff and community and subsequently builds support for services to children (Kelly, 1995).

Funding

Without a major change in health care policy, a comprehensive school health program will seldom be funded to fully meet the present needs and growing demand. School-based health programs cost between $100,000 and $300,000 a year, depending on the size of the school and the comprehensiveness of the program (Dryfoos, 1994). As those who govern schools seldom mandate such programs, developing funding sources for school health programs becomes an important issue. Although most school-based centers must seek multiple financing arrangements, obvious places to start would include the local school board and the local private sector. The local school board may provide seed money yet cannot be depended on as a long-term funding source. An exception may be that if the board's hope is to fully integrate health promotion into the existing curriculum then more permanent funding may occur. Otherwise, the private sector, which includes United Way, corporations that wish to maintain and enhance their communities, and private foundations, may be more reliable and permanent resources.

Several states have adopted laws or officially supported the development of school-based clinics (Dryfoos, 1994). States may use either federal block grants or establish their own state block grants to fund such programs. In general, state agency grants tend to be much shorter, less complicated, and less time consuming than federal grants. The grants supported by states almost always follow the "residual model" (a problem causing one to resort to public assistance). Thus, to obtain a grant, one needs to document problems with drug and alcohol, at-risk youth, etc., in order to obtain funding.

Nationally, funding is typically more complex. Federal grants may be more inclusive yet typically more complicated and involved. If a school is providing medically necessary services to children and families that are Medicaid eligible, then the school could be eligible to receive reimbursement from Medicaid for eligible services and administrative supports (Wrobel & Kreig, 2000). These funds can be substantial and should mean that more children have access to health care and the health care programs that could be provided by the schools. Managed care is another option. It is possible that school-based services may overcome the hurdles of managed care in order to ensure that school-based clinics or programs are certified as providers for students whose parents are enrolled in a managed care plan.

The Centers for Disease Control (CDC) provides resources to ensure that their identified curriculum to reduce risk behaviors is available for state and local agencies interested in using them. Presently, the CDC directly funds 16 states for coordinated school health programs (funding for HIV-AIDS prevention in schools alone accounts for approximately $47 million). The Surgeon General is a strong advocate for health care, and although health care reform failed under the Clinton administration, national health care reform remains a vital agenda item on the federal scene. A comprehensive school health curriculum or health education programming is prevention and may be attractive to both the liberal and conservative elected officials.

BEST PRACTICES

In her book, *Common Purpose,* Lisbeth Schorr (1997) outlines the Seven Attributes of Highly Effective Programs, that I believe set the foundation for this chapter. These attributes (pp.5 –10) are as follows:

1. *Successful programs are comprehensive, flexible, responsive, and preserving.* While they do not try to provide everything to everyone, they are flexible, and offer more than a single strand of service or support. They often think beyond professional services and help families to strengthen bonds with neighbors and churches and other natural networks of support.

2. *Successful programs see children in the context of their families.* Effective programs are alert to the family context. They are aware that whether a child's health needs will be met depends on the coping abilities, mental health, and social and economic resources of the parent. Although enlisting the overwhelmed and overstressed parents of today requires more skill than ever before, school programs must recognize the need for deeper parent involvement.

3. *Successful programs deal with families as parts of neighborhoods and communities.* They grow deep roots in the community and respond to the needs identified by the local population. They are not just *in* the community but *of* the community so that "best practices" are often whatever works in a given context.

4. *Successful programs have a long-term, preventive orientation, a clear mission, and*

continue to evolve over time. Successful health promotion programs would primarily focus on the period from pregnancy through elementary school as the most productive time to intervene. They combine a highly flexible mode of operation with a clear sense of mission and don't abandon their fundamental mission for the fad of the moment. They maintain a stable core and share common beliefs yet adapt strategies based on the changing needs of individuals, families, and communities to reach the goals agreed upon.

5. *Successful programs are well managed by competent and committed individuals with clearly identifiable skills.* Directors of successful programs don't do it by magic or charisma but by using identifiable management techniques to create a coherent, outcome-oriented mission. They inspire staff with a shared vision of the program. Their skills are not a mystery and can be learned. They include a willingness to take risks, to tolerate ambiguity, and to win the trust of staff and the public.

6. *Staffs of successful programs are trained and supported to provide high-quality, responsive services.* Needing to be versatile and flexible, a greater discretion is given to staff. Yet, training, monitoring, and supervision are emphasized to ensure that the discretion exercised keeps with mission goals and high standards or quality. Thus, flexibility is built on competence.

7. *Successful programs operate in settings that encourage practitioners to build strong relationships based on mutual trust and respect.* Often a special relationship is at the core of the successful program. Although rarely explicitly stated, caring and relationships are often the most important aspects of a program. Last, the author points out that a spiritual dimension to the relationships contributes to fostering change.

Coordinated School Health Programs

Consistent with the belief that the most effective form of school health education is "comprehensive school health education," the Centers for Disease Control and Prevention conceives of health education as eight interactive components, including health education, physical education, health services, nutrition services, health promotion for staff, counseling and psychological services, healthy school environment, and parent/community involvement (School Health Programs, 2000). The program is consistent with Schorr's (1997) criteria in terms of comprehensiveness, mission, prevention, and utilizing the context of family and community. The program is well documented, planned, and offers a sequential program of health education for students at every grade level, kindergarten through 12. Although Congress has been most keenly focused on the health services and health education components, aside from the obvious focus on counseling and psychological services, the components of health promotion for staff and the healthy school environment are definite inroads for the school psychologist.

Kolbe et al. (1997) note that the CDC is working with other federal agencies, national organizations, and state and local departments of education, health, and social services to improve delivery of the eight components. Their strategies include (a) identifying and monitoring critical health-related events and school interventions affecting those events, (b) integrating and applying research to increase the effectiveness of interventions, (c) providing the means for relevant constituencies to plan and implement interventions, and (d) evaluating the impact of the interventions over time. Working together toward common goals is a thrust of the CDC. In 1992, CDC began providing fiscal and technical support to selected state departments of education and departments of health to jointly help school districts implement the eight components of school health programs (Kolbe, et al., 1997). In the year 2000, CDC is providing assistance to 16 states: Arkansas, California, Florida, Kentucky, Maine, Michigan, Minnesota, North Carolina, New Mexico, New York, Ohio, Rhode Island, South Carolina, South Dakota, Wisconsin, and West Virginia (School Health Programs, 2000). The CDC helps all 50 states and hopes to provide comprehensive support to all states in the near future. As school psychologists are trained across many of the psychological disciplines, they are considered to be "indispensable members of the school health team" (Kolbe et al., 1997, p. 263).

Mental Health Models

This section is written for those of us who wish to focus more on mental health/emotional services rather than on the larger spectrum, which would include physical and spiritual health. It is becoming clear that the current system of providing mental health services is not efficient and is not working effectively. By using a conservative prevalence rate of 9–13% for serious emotional disturbance, O'Day (2000) notes that, in an elementary school of 600 students, between 54 and 102 children would be in need of psychological/mental health services. Even if assigned full-time to one school, the need and the caseload would overwhelm the school psychologist. Using an individual problem-solving model might be an improvement, yet any focus on treatment or individual intervention would eventually overwhelm the psychologist and the system. Thus, a transformation in the delivery of school psychological services will be necessary to address mental health/emotional–related needs.

Zins and Wagner (1997) recognize the full spectrum of health services while providing numerous examples of mental health activities for the school psychologist to choose:

1. Helping with transitions such as moving from elementary to junior high school;
2. Developing interventions with groups of students in areas such as problem-solving, conflict-resolution and social skills, and helping create a supportive, safe environment in which these can occur;
3. Determining the availability of alcohol in the community and identifying establishments that have a history of serving or selling;
4. Implement programs to prevent smoking, alcohol use and/or premature sexual activity;
5. Teaching behavioral self-management skills to reduce violence or loss of control;
6. Providing program evaluation services to assess the outcomes of health promotion efforts;
7. And, providing instruction in stress or time-management (pp. 949 –950).

Even though most of us were trained in many of these areas in terms of pathology or remediation, the promise of the prevention of problem behaviors and promotion of healthy ones must assume greater importance. Zins and Wagner (1997) note that modification in orientation and skill applications is more often required of the traditionally trained school psychologist rather than extensive new coursework.

Two programs that follow a mental health orientation are worthy of note. Communities That Care (Hawkins, Catalano, & Associates, 1992) is a program that was developed for every person concerned about the healthy, drug-free development of our nation's children. The program is noteworthy inasmuch as it examines health promotion from the perspective of protective mechanisms and risk factors. Further, Communities That Care requires the active involvement of whole communities (mayors office, business leaders, police, health professionals, etc.). Its greatest asset is the bringing together of diverse community members with the common mission of making their community a protective environment for the healthy development of its young people.

Social Problem Solving and Social Decision-Making Project (SPS-SDM) has spread from a demonstration project to one that now includes hundreds of classrooms in nearly half of the states (Zins, Elias, Greenberg, & Weissberg, 2000). The original curriculum developed by Elias and Clabby (1989) was focused on classroom-based interventions in which school psychologists and teachers collaborated. The program was awarded the 1988 Lela Rowland Prevention Award and has been designated as a model program in the National Mental Health Association prevention Clearinghouse, the U.S. Department of Education, and the National Educational Goals Panel (Zins et al., 2000).

The core of the project is the building of social and emotional skills in elementary students. Students are taught self-control, group participation and social awareness, and a decision-making strategy that they can use when faced with difficult choices. The program has a strong prevention orientation, and the social and emotional components require students to integrate behaviors (actions), cognition (thinking), and emotions (feelings) to achieve specific goals. Examples of skills associated with social and emotional learning (SEL) include (Zins et al., 2000, p. 76):

1. Being aware of other's feelings
2. Accurately perceiving the perspectives of others (empathy)
3. Possessing assertiveness and a sense of self-efficacy
4. Ability to cooperate with others and resolve conflicts peacefully

In an attempt to help students develop the skills that a socially competent student might possess, the program has developed modules. Examples of these modules are (Zins et al., 2000, p. 89):

1. A program that allows students to create school and community service projects
2. A video program that shows children how to watch and analyze television programming and use their social decision making and problem solving skills to create their own programs, etc.
3. A "FIG TESPN" approach—an acronym for Feelings as a clue that a problem exists; *I* may have a problem; Goals to guide actions; *T*hinking of things to do; *E*nvisioning outcomes for each identified solution; *S*elect the best solution in relation to one's goal; *P*lan to implement; and *N*ext time will I do the same or try a different approach.

The program has been in existence for nearly two decades, and extensive research has documented the effects of the SPS-SDM program. Results of the studies that have been performed speak highly of the program. Data have shown that children, teachers, and other educators enjoy the program and put its principles to frequent use (Zins et al., 2000). Studies have been conducted in terms of pre-test to post-test gains where children involved in the program were compared with those children who did not participate. In general, examples of gains for children involved in the program include better transitions to middle school, increased self-esteem, and better social awareness (i.e., empathy) and social decision making.

Physical Activity and Diet

Health is a construct and is composed of many complementary behaviors. The separation of mind and body makes little sense to one serious about studying health. Yet, where does one start when organizing a health promotion program? If a community is knowledgeable and sees that health is a construct that includes physical, mental health/emotional, and spiritual components, then the starting point may not be a central question, and, as noted before, a comprehensive approach is best. However, we would argue that the safest point to start in most communities would be in the physical health and nutrition arenas.

David Satcher, U.S. Surgeon General, on March 15, 2000, argued what follows in the "Opinion" section of the *Atlanta Journal-Constitution*:

> I am alarmed by the steady trend we have seen over the last two decades toward decreasing physical education requirements in public schools... fewer schools require students to engage in physical activity at school... currently, no state mandates daily physical education in grades K–12, and participation by adolescents in grades 9-12 in daily physical education has declined dramatically... by about one-third, from 42 percent to 27 percent between 1991 and 1997... combined with an American diet that is too heavy on sweets and fats and too light on fruits and vegetables, have raised obesity to epidemic proportions in the United States.... We need to create environments where healthy lifestyles are as easy to adopt as unhealthy ones (p. A17).

Not surprisingly, children who participate in regular physical activity have more favorable cardiovascular disease risk factors than less active children. Saunders and Pate (2000) make the point that eating habits that begin in childhood contribute to a multitude of chronic diseases in adulthood (e.g., heart disease, cancer, and osteoporosis). Finally, numerous physical and nutritional policy statements call for lifetime physical activity and improved daily nutritional choices, and professional development for those involved in physical education and nutritional education.

Saunders and Pate (2000) identify the Child and Adolescent trial for Cardiovascular Health (CATCH) project as a model program to promote physical activity and healthful eating in a school setting. CATCH is implemented grades 3–5. Their food program (Eat Smart) focuses on reducing the fat and sodium content of food served. Their physical education component is geared to increase the amount of time that students engage in moderate to vigorous physical activity. The project also adds a home component to complement the classroom curricula. In a 3-year follow-up study, students in the intervention group maintained higher levels of physical activity and dietary intentions than those students in a nonequivalent control group.

Physical Focus and Physical Dimensions (2000) are curricula designed for sixth to eighth (Physical Focus) and ninth (Physical Dimensions) graders to promote knowledge and skills to enjoy a physically healthy lifestyle. Physical Focus centers on level of fitness, regular habits of physical activity, cooperative and competitive activities, and life-long skills. Physical Dimensions includes physical activity, diet, and a wellness component. An exciting element of the Physical Dimensions program is the High School Ph.D., a certificate of achievement given to graduates of the program.

Positive Youth Development

High rates of boredom, alienation, and disconnection from meaningful challenge are typically not signs of psychopathology, but rather signs of deficiency in positive youth development (Larson, 2000). Larson makes the argument that one could engage in a similar debate surrounding many cases of problem behavior, such as drug use, premature sexual activity, aggression, depression, and minor delinquency. Larson, as a developmental psychologist, finds the answers to the problems of today's youth more in an absence of a positive life trajectory than in the most common explanations of emotional disturbance, maladaptive cognitions, or as a response to family stress. The Carnegie Council on Adolescent Development (1992) has made positive youth development a hot term on the national scene, yet psychology has been slow to respond. Consistent with our negative focus on how "things go wrong" for youth, psychology has neglected the positive. Larson (2000), however, sees a diffuse body of research on the pathways whereby children and adolescents become motivated, directed, socially competent, compassionate, and take charge of their lives. Positive youth development is a movement that is enabling youth to explore these pathways.

Owing to a plethora of internal and external factors, most schools have also failed to respond to the challenge of the positive youth movement. As alluded to before, today's schools are so focused on the development of academic skills that health promotion and the benefits of extracurricular activity are often ignored. In 1990, the National Educational Longitudinal Study (see Zill, Nord, & Loomis, 1995) noted that the average tenth grade student spent less that one hour a week in an extracurricular activity (sports, music, art, drama clubs, as well as community service). While involvement in extracurricular activities has been clearly demonstrated as beneficial (Carns et al., 1995) in terms of reducing high-risk behaviors, and increasing academic success and building desirable character traits, its benefits are not being promoted or taken advantage of by a significant number of today's youth.

Children and adolescents are often out of school and home unsupervised by 3:00 p.m., and a number of problems have developed. By using juvenile crime rates as an example, the Federal Bureau of Investigation has found that the hours between 3:00 p.m. and 8:00 p.m. are the peak hours for violent juvenile crimes (Fox & Newman, 1997). As an alternative, Zill et al. (1995) have argued that participation in after-school programs can offer children and adolescents a vast number of skill- and character-building opportunities while diverting them away from delinquent behaviors. Thus, the need for after-school programming is clear and becomes a challenge for both schools and communities.

A community-based asset approach to building positive youth development is a joint project of Lutheran Brotherhood and the Division of Congregational Ministries of the Evangelical Lutheran Church in America. The Search Institute (2000) has identified 40 developmental assets that young people need to build to be healthy and successful. The assets are divided into two broad categories: external and internal. External assets are support (e.g., a caring neighborhood), empowerment (e.g., service to others), boundaries and expectations (e.g., positive adult role models), and constructive use of time (e.g., creative activities). Internal assets are commitment to learning (e.g., achievement motivation), positive values (i.e., promoting equality), social competencies (i.e., empathy), and positive identity (e.g., self-esteem). The focus of the program is to build these assets in a congregation, and yet extensive interaction with one's community is encouraged.

The Search Institute makes a convincing case that assets make a difference. Having collected data from almost 100,000 sixth to twelfth grade public school students in 213 towns and cities in 25 states, it is evident that patterns of risk-taking behavior and positive behaviors and attitudes are altered by the number of assets that youth report. For example, youth that report only 0–10 assets have the highest rates of illicit drug use, rates of violent behavior, and depression/suicide attempts. Conversely, students reporting 31–40 assets, have the lowest rates of illicit drug use, aggressive behavior, and rate of depression/suicide attempts. In terms of positive behaviors and attitudes, the findings again strongly favor those youths reporting the greatest number of assets. For example, the more assets, the more likely the youth is to help others, earn high grades in school, maintain good health habits, and value diversity.

The final project to be addressed in this chapter is a more scientific approach to positive youth development. Larson (2000) believes that *initiative* is a core requirement for other positive components of development, such as health choices, leadership, altruism, and civic engagement. Today, images of adult careers do not have enough magnetic pull, in and of themselves, to motivate most youth to begin taking control of their lives. Further, given that the future of many occupations is unstable (many may not exist in 20 years), it is better that youth are motivated by initiative than by anticipated long-term rewards.

Initiative is the dedication of cumulative effort over time to achieve a goal (Larson, 2000) and is composed of three elements. Initiative involves *intrinsic motivation* or wanting to do an activity and being invested in it. Second, a *concerted engagement* or thought and effort toward creating some form of order, synergy, etc., in the environment is required. Third, initiative involves a *temporal arc of effort* or the capacity to re-evaluate and adjust strategies. Larson notes that to become an agentic adult (a person capable of being an agent of change), one needs to be able to mobilize one's attention, one's mental powers, on a deliberate course of action, without being deterred by the first obstacle one encounters. He later further summarizes these terms as intrinsic motivation, concentration, and challenge.

Larson confirms that the great majority of adolescents' time is spent in two opposite experiential domains. In school, they experience concentration and challenge without being intrinsically motivated. In most leisure activities, including watching television, they report experiencing intrinsic motivation but a lack in concentration and challenge. An exception is what he terms structured voluntary activities, including youth organizations and extracurricular activities. The defining criteria for voluntary structured activities were those with rules, constraints, goals, and activities where the youth were highly motivated to be involved. Sports, arts, music, hobbies, and participation in organizations were all perceived as involving high intrinsic motivation, concentration, and challenge. Larson concludes that such activities are critical to positive youth development.

In addition to the development of initiative, Larson reviews a range of research to confirm that structured voluntary activities are associated with multiple positive outcomes including diminished delinquency, greater achievement, and increased self-control and self-efficacy. Next, he reviews research by Heath (1999) that has recorded language use and has found that adolescents participating in structured voluntary activities acquire a new operating language of agency that reflected an increased ability to affect the world. For example, when the youth first joined a structured voluntary activity their statements included little conjecture about future events and a passive and self-defensive orientation that viewed acts of initiative as doomed to failure. Within four weeks, language use that reflected skills to think about the world as a field of action increased.

Larson's research and his review of the research of cohorts examining structured voluntary activities paints a positive picture of early adolescents that are awake, alive, and open to developmental experiences less common in other parts of their lives. He believes that the agentic states developed by voluntary structured activities make for a fertile ground for adolescents to develop and teach themselves a wide variety of positive health competencies. Our challenge is to help find those activities that contain the elements of intrinsic motivation, concentration, and challenge and expose youth to these elements. A further challenge will be to find ways to incorporate those elements into a school health curriculum that will send today's youth toward a future of spiritual, mental/emotional health, and physical health.

SUMMARY

Today's youth are grossly underserved in almost every arena of health promotion. When a decision is made to support an "academic" area or remedial program versus a health area, the health area is far too often the loser. Yet, research demonstrates that we are approaching a time when emotional, physical, social, and spiritual health of our youth is arguably more important than basic cognitive skills and far more cost effective than remedial programming. Children of today are more at-risk and self-report more emotional problems, delinquency, and problem behaviors than the reports of youth from previous generations. The good news is that solutions do exist, and yet the described solutions will require significant changes in our current practice.

In this chapter we have defined health and demonstrated its manifestations. We have explored the present status of health promotion and have offered numerous models for change. In our review we have found that integrative, comprehensive, and primary school level programs are best and that preventative efforts are vastly preferred over reactive or remedial efforts. Schorr (1997) cautions that even highly successful programs cannot be transplanted wholesale from one setting to another and be expected to work. Needs for health promotion must be defined by the local population. Minke (2000) notes that this does not mean, "reinventing the wheel." A number of excellent programs do exist, and their mission statements and/or theoretical orientations are clear. Find the program or philosophy that may work in your school and community. Network with teachers, parents, principals, and community agencies that are committed to implementing a health promotion program in your school or community. Together, envision what comprehensive school health education can be and bring it to fruition.

ANNOTATED BIBLIOGRAPHY

Dryfoos, J. D. (1994). *Full-service schools: A revolution in health and social services for children, youth, and families.* San Francisco: Jossey-Bass.
Perhaps the most comprehensive book on full-service schools. Makes a strong argument for broad based health promotion and is filled with ideas on how to make a full-service school a reality.

Schorr, L. B. (1997). *Common purpose: Strengthening families and neighborhoods to rebuild America.* New York: Anchor.
Required reading for anyone interested in solutions to the social problems plaguing our nation. Research based, practical, and optimistic.

Search Institute. (2000). *Take it to heart: An asset-based guide to nurturing children, youth, and families in faith community.* [Brochure]. Minneapolis, MN: Author.
One of a number of brochures and newsletters published by the Search Institute. Highlights positive youth development and offers 40 assets that all youth in America need to possess.

U.S. Department of Health and Human Services (1999). *Mental Health: A report of the Surgeon General.* Rockville, MD: U.S. Department of Health and Human Services, Substance Abuse and Mental Health Services Administration, Center for Mental Health Services, National Institutes of Health, National Institute of Mental Health.
The 487 page document makes a convincing argument (using research articles and other documents) that mental health has a direct link to the learning process and to learning outcomes. May be a valuable source to help convince a broader constituency that mental issues must be addressed if our children are to succeed in school and life.

Zins, J. E., & Wagner, D. I. (1997). Health promotion. In G. G. Bear, K. M. Minke, & A. Thomas (Eds.), *Children's needs II: Development, problems, and alternatives* (pp.945–954). Bethesda, MD: National Association of School Psychologists.
Chapter in an earlier NASP publication that focuses on the full spectrum of health-related issues that affect our children. Their definition of health promotion remains the standard. They convincingly argue that our current system is not working effectively and that school psychologists must play a central role in reducing the many health risks faced by today's youth.

61 Best Practices in Developing Exemplary Mental Health Programs in Schools

Kathy Pluymert
West Dundee, IL

OVERVIEW

The need for school-based mental health services has become increasingly apparent in recent years. As school communities, parents, policy makers, and the media have examined factors that may account for incidents in which a crisis has occurred in a school setting, a recurring theme has been the mental health needs of the students involved. High-profile crisis situations are dramatic illustrations of the struggles that school communities encounter daily in trying to help students succeed in school in the face of sometimes overwhelmingly complex personal and social difficulties.

In some situations, a high-profile incident that captures the media spotlight or a crisis in its own community is what propels the school to develop programs to address the mental health needs of students. In the wake of a crisis, members of the community are searching for ways to prevent those kinds of tragedies from ever happening again. The Chinese symbol for crisis, which includes elements of both danger and opportunity, illustrates the challenge to school communities, and to the profession of school psychology in these situations. Members of the National Association of School Psychologists (NASP) National Emergency Assistance Team observed, "Crisis has been frequently recognized as a time of potential danger as well as potential opportunity.... If our profession is able to manage the danger—that is, manage the immediate crisis and quickly return the system to normal functioning—then there exists a tremendous opportunity to stimulate long-term systemic change. Once seen as effective and credible, the psychologist has infinitely more opportunity to move the system in the direction of prevention" (Poland, Pitcher, & Lazarus, 1995, p.446).

While tragic situations may sometimes be the impetus for developing school-based mental health programs, there is a growing body of compelling evidence in our society of the importance of addressing mental health needs of children. Demographic information collected by a host of private and government agencies clearly demonstrate the need for interventions and systematic approaches designed to address child and adolescent mental health needs. Statistics related to poverty, family disintegration, violence, and substance abuse are staggering indicators related to the lack of supportive families and economic resources needed for learning and school success (Knoff, 1996; U.S. Department of Health and Human Services, 1999). These barriers to learning (Adelman, 1996) are a growing concern in our society.

School psychologists can be an outstanding resource to the school community in the development of effective mental health services to address the needs of students and families. The challenge lies in providing excellent service in a crisis and also on a day-to-day basis in the routine matters and small crises that builds the credibility of the school psychologists within the school community.

Providing mental health services, such as group and individual counseling and mental health evaluations, have been a part of school psychological training and professional practice throughout the history of the profession. More recently, a growing body of literature that addresses the role of school psychologists as mental health service providers has emerged. Both literature and practice show that school psychologists are providing mental health services across the spectrum from prevention to treatment. These services can be found on a small scale in a single school and in complex exemplary school-based mental health programs that integrate the services of the school, community agencies, hospitals, and universities (Nastasi, Varjas, Bernstein, & Pluymert, 1998).

There is an increasing level of awareness among mental health professionals across sub-specialties that schools are a logical place for the delivery of mental health services to children and youth. Mental health services offered to students in school settings is a common sense service delivery option because children and youth are required to be in school. Providing mental health services in the school setting affords some excellent solutions to problems that families have in accessing mental health services, including problems with transportation and financial resources needed to obtain these services in the community (Dryfoos, 1994). As Knoff and Batsche (1990) point out, schools also provide excellent settings in which to identify and treat students with mental health needs as the school setting provides many opportunities to integrate and monitor treatments across home, school, and community settings.

Mental health services within school settings have the distinct advantage of presenting an ecologically realistic setting in which interventions can be readily integrated into students' daily activities. This integration allows for opportunities for students to generalize behaviors and skills learned in therapeutic sessions into their daily routines, allowing for greater integrity in their overall functioning (Jackson & Bernauer, 1975). In addition, mental health professionals who work with students in school settings can, in collaboration with teachers, recommend and evaluate the effects of modifications to the classroom environment. It might also be possible to modify the expectations and attitudes of school personnel through consultation, providing data about the student's needs and learning styles, and modeling.

There is an increasing awareness of the value of school settings as important in meeting the mental health needs of children and youth. Many mental health professionals, who 15 years ago would not have considered providing services in schools, are now very interested in school-based mental health because of the benefits to children and disenchantment with more traditional forms of mental health service delivery systems for children (Waxman & Weist, 1999). In addition to the benefits to students of providing mental health services in schools, there are other economic and professional factors that serve to draw professionals previously serving in private practice and clinical settings to the school. The advent of managed care and subsequently limited or reduced funding for mental health services to hospitals and private practices have also resulted in the schools now being perceived as an attractive practice setting to mental health professionals and psychologists of other specializations (Bricklin et al., 1994; Short & Talley, 1997). Unfortunately, many of these professionals have minimal training and experience in working with children and little familiarity with school settings. While there is some acknowledgment among psychologists that there is a specialized set of competencies in school practice (Kubiszyn, 1999), the future of school-based mental health services will likely be much more a matter of well–conceived and collaboratively implemented mental health services delivered in the schools by a group of mental health specialists across disciplines.

From the perspective of both child and professional advocacy, it is vital that school psychologists become proactive in promoting their role as mental health service providers and in the development of exemplary mental health programs in schools (Dwyer, 1996; Gutkin, 1995). Realistically, professionals who are the most versatile, who can provide the most valued and cost-effective services to the district, and who are able to demonstrate the efficacy of their services to decision makers are those who will be asked to serve the school community, without regard to an individual's training or title.

Given the need for school psychologists to be increasingly proactive in the development of exemplary school-based mental health programs and services, the purpose of this chapter is twofold. First, to serve as an introduction to the practitioner on the resources and literature available that describes school-based and school-linked mental health services and programs currently in school settings. The second purpose of the chapter is to provide practical strategies that school psychologists can use to develop an approach integrating mental health services and programming into their own school community to address the unique needs of the local educational agency they serve.

BASIC CONSIDERATIONS

Before a school psychologist can begin to develop a school-based mental health program, there are a number of factors that the practitioner needs to be cognizant of to maximize the likelihood of the long-term success of a program and to minimize frustration and road blocks to the process. These factors include: (a) building a foundation of credibility and trust within the district, (b) knowing how the school functions as a system and understanding its unique needs, (c) building coalitions and networks for comprehensive and coordinated service delivery options, and (d) becoming well prepared to plan, implement, and evaluate the services and/or program. If the practitioner attends to each of these factors, then the program has a much greater chance of institutionalization. That is, the program will be accepted, implemented as designed, integrated, and valued by the school and community and will survive challenges that will come in the form of changes in staffing patterns, funding, and leadership/administration within the system.

Build a Strong Foundation of Trust

One of the questions most frequently asked by school psychology practitioners is, "How can I get my supervisor/principal/school district to let me provide mental health services? It's not part of my job description." The answer to that question is twofold and has to do with providing excellent services and being willing to take a risk to go beyond the stated job description. The most effective advocates for the profession of school psychology are skilled in two ways. First, they are caring, competent school psychologists who provide excellent forward-thinking services to children and the school community. Second, they are skilled in demonstrating the value of their services to the system in which they work and actively do things to build positive relationships with others. It is vitally important that school psychologists raise their visibility in the school community in which they work, because increased visibility can lead to increased opportunities to expand their role and to serve children.

There are several excellent resources that practitioners can use to become intentional about building positive relationships and developing communications activities that will serve to illustrate the value of their services to the school community. For example, NASP members can access several resources from a NASP manual entitled, *Practical Strategies to Expand Services to Children and Families* (Thomas, Pluymert, & Armistead, 1998). This manual includes examples of communications activities such as model newsletter articles, samples of letters, and prepared presentations (including overheads) that can be used as they are or modified to suit the needs of the individual practitioner. As school psychologists use these kinds of communications activities to educate decision makers in the community about their expertise and knowledge base in key areas of mental health service delivery, the better their position will be as new opportunities present themselves. In addition to purposeful communications activities, school psychologists need to make purposeful positive personal contacts with decision makers. It is important not to underestimate these contacts (Curtis & Stollar, 1995).

For example, one school psychologist began by regularly scheduling only 15 minutes each week to talk with the building principal about building-level issues. After a few weeks of such talks, an interesting journal article related to one of the issues discussed would occasionally be given to the principal. Over time, the school psychologist came to be viewed by the principal as a source of information and expertise regarding a broader range of issues, particularly as they pertained to organizational concerns (p. 55).

Understand the School Community as a System and Know What the Community Needs

The long-term success of school-based mental health programming depends largely on the program becoming integrated into and valued by the system. To achieve the goal of institutionalization of mental health programs, it is critically important to attend to systems issues and needs assessment in the development, implementation, and evaluation of these programs.

DEVELOPING A SYSTEMS ORIENTATION

Curtis and Stollar (1995) offer the following definition of a systems orientation: "a systems perspective involves the ability to understand the reciprocal influence that the various parts of a system, the system itself, and the surrounding system or environment exert on one another" (p.52). When considering the development, implementation, and evaluation of mental health programs, a systems perspective is important for several reasons. One of these is that implementing mental health programs in schools is essentially a form of system-level consultation. A problem-solving approach, collaboration, and systematic planning are critical skills that a practitioner needs to develop mental health services in school settings. Another reason that a systems perspective is vital is that reciprocal effects of the multiple facets involved in mental health programming need to be considered. Factors such as the effects of family environment, the school, and the community on the students, as well as the impact that students have on their respective environments, are important considerations (Meyers & Nastasi, 1999). Including active participation of key individuals who are decision makers, influential in the community, and determine access to financial resources as well as any group that will be involved in the program (or affected by it) is also vital if the program is to be valued and supported by the system. The reader is referred to the chapter on system-level consultation in this volume for further information about these important skills.

CONDUCTING A NEEDS ASSESSMENT

If a mental health program is to be successful, then it is essential that the program be tailored to the unique needs of the school community, students, and families it is designed to serve. The practitioner needs to look for a convergence of information from a variety of sources to establish the real and perceived needs within the school community from a variety of perspectives. There are several needs assessment methods that can be used to gather this kind of critical information. School psychologists have a natural source of information in the kinds of referrals that are a part of their work in the school system. An analysis of formal and informal referrals for consultation services, problem-solving meetings, pre-referral intervention team meetings, case study evaluations, or "hallway consultation" provide a rich source of information about needs in the community. By keeping track of referrals, case load, and investigating the records of building-level team meetings, from Teacher Assistance Teams to multidisciplinary staff conferences, a pattern of needs will emerge. Information from disciplinary referrals, suspensions, and expulsions will add a substantial amount of information available if it is compiled and analyzed carefully. Data can also be collected from community-based or county resources such as the Department of Corrections, Department of Health, and Social Services. The data about rates of violent crimes, juvenile arrests, substance abuse, adjudicated youth, and teen pregnancy are important information about student mental health needs and assist the psychologist in developing the perspective of the school as a part of a larger community.

Additional perspectives can be gained through interviews with parents, policy makers, and other important decision makers in the school community. Those interviews can be informal conversations, formal structured interviews, or in focus groups. The interviews serve not only to provide information, but to demonstrate that the school psychologist is interested in building collaborative relationships. The field of school-based mental health service is changing and developing at a pace somewhat faster than educators typically proceed, which can lead to some resistance. Be sensitive to this during the interviews. Another factor to consider is that there are groups that object strenuously to mental health services delivered in schools (Evans, 1999), and their perspectives also need to be attended to in the development of school-based services.

Finally, surveys can provide a concrete form of gathering information about both real and perceived needs through collecting specific system-level data and attitudinal information from members of the school community. Nagle (1995) provides an excellent overview of needs assessment techniques for school psychologists that could be used to gather the information needed for mental health program development.

Build Coalitions and Networks for Comprehensive and Coordinated Services

Given that programs and services for children and adolescents are provided by a variety of sources, it is common for any individual child to be served by multiple agencies and service providers within the community that are not in communication with each other. To address the problems of streamlining and increasing the efficacy of mental health services, the current watchwords are "coordinated and integrated services" (Bickman & Rog, 1995). Schools provide an excellent setting for collaboration and coordination of services for children and youths. Schools can serve several functions including complement services of outside agencies, serve as a catalyst to coordinate services, and develop programs to improve and expand services delivered in the school setting (Adelman, 1996). As Conoley & Conoley (1991) observed, the nature of referrals and range of presenting problem behaviors are the same for school-based and clinic-based psychologists. Through working together, school, clinic, hospital, and community agency-based mental health practitioners may have the opportunity to improve treatment outcomes by coordinating interventions across the home and school settings.

The development of comprehensive and coordinated mental health service delivery models requires that school psychologists be well acquainted with the services and agencies already available within the community. School psychologists need to know which community agencies, parent and family support groups, and private providers (including pediatricians and pediatric specialists) exist in the community and what functions those agencies and groups provide to students and families. It is also important to begin to build relationships with those groups to open the door to further communication during the planning, implementation, and evaluation of school-based or school-linked mental health services and programs. Getting to know community resources is not only a form of needs assessment, but it is an important aspect of program development through coalition building. Child advocacy and coordination of services require that school psychologists do this kind of networking in serving individual students. Similarly, coordination and coalition building is needed when developing services for the school community. Look for ways in which the needs of children, teens, and families are being met in the community. Conversely, look for unmet needs and ways that existing programs and services could be improved.

Do Your Homework on Effective Mental Health Services

The Scouting motto "be prepared" offers wise counsel to school psychologists who are working to establish or expand mental health services in school settings. Once the practitioner gets a sense of the needs of the students and the school community served in his or her local education agency, and understands the existing supports and services available, it is critical to begin to investigate effective practices, service delivery systems, and programs that work. While there is merit in creative approaches and innovative programs, the stakes for children and families who have significant mental health needs are high. The field of mental health services has evolved to the point where there is an extensive body of evidence about effective interventions and programs to address the mental health needs of students and families that yield good outcomes (Hoagwood & Erwin, 1997).

The literature of school-based and school-linked mental health has grown tremendously in the last decade, with good material added regularly. It is difficult to recommend one book or journal over another, since there are many equally good sources from which to choose. However, for a good basic orientation to the literature in school-based mental health services, the brief annotated bibliography and list of references at the end of this chapter can serve as a good starting point. The annotated bibliography was chosen to give an overview of some of the theory and practice in school-based mental health with an emphasis on literature outside of material that a typical school psychologist practitioner might read. For information about specific kinds of programs, for example, to address suicide prevention, or crisis intervention, in addition to the resources in this volume, conduct a literature review by using ERIC, PSYCHINFO, or other similar databases, many of which can be accessed on-line though a school or university library. The information gained through literature review will provide invaluable information about how to design, implement, and evaluate a program or service, and will provide a kind of benchmark, and perhaps rationale, to use as a pattern. This is also an important consideration in funding, because many funding sources may require the replication of an existing program model.

One good resource to obtain information about existing mental health programs is Nastasi, Varjas, Bernstein, and Pluymert (1997). Nastasi et al. (1997) includes information about many programs across the United States. An example of one frequently cited model developed by school psychologists is Project ACHIEVE. A program description can be found in

Knoff and Batsche (1995). Finally, there are several agencies or organizations that can be accessed via the Internet that have information about school-based mental health programs. In addition to NASP's National Mental Health and Education Center for Children and Families, the American Institute for Research, School Mental Health Project/Center for Mental Health in Schools (University of California, Los Angeles), and the Center for School Mental Health Assistance (University of Maryland School of Medicine) have excellent resources. Another resource includes a multi-million dollar grant program funded by the U.S. Department of Education that was designed to address reduction of school violence through a collaborative school- and community-based mental health program. Obtaining a grant from these funds, The National Mental Health Association and NASP, working together with several other agencies, developed a network of school-based mental health programs called, "Safe Schools/ Healthy Students Initiative." This initiative provided many exemplary comprehensive and coordinated school and community mental health programs for a 3-year period, beginning in 1999, and provides examples of many good model programs.

BEST PRACTICES

There are many excellent program models, theories, and best practices in mental health services for children and families. What follows is a summary of a consensus of opinions and theoretical and practical considerations in developing, implementing, and evaluating an exemplary mental health program. The following factors are important best practices in the process: (a) attend carefully to characteristics of exemplary programs (b) choose well-documented models and/or empirically validated interventions, (c) pay close attention to legal considerations, (d) develop a blended funding base, and (e) complete program evaluation and use the data to further develop the program and to promote the program in the school community.

Characteristics of Exemplary Mental Health Programs

According to Nastasi et al. (1997) , there are six hallmarks of exemplary mental health programs:

1. Programming reflects an integration of theory, research, and practice.

2. Programming is framed within an ecological-developmental theoretical model.

3. Program development, implementation, and evaluation reflect a collaborative/ participatory model.

4. A continuum of mental health services is provided, ranging from prevention to treatment.

5. Program evaluation address program acceptability, integrity, and effectiveness.

6. A school psychologist is involved in one or more aspects of mental health programming.

What follows is a summary of the description of each of these factors from Nastasi et al. (1997).

INTEGRATION OF THEORY, RESEARCH, AND PRACTICE

If a mental health program is to be exemplary, it is essential that there be an integration of relevant theory and research, and application of these into the daily workings of the program. This process is a cycle of learning, planning, implementing, and evaluating practice in light of developing theory, results of evaluation and related research, and subsequent modification of practice. This collaborative action research approach (Meyers & Nastasi, 1999) is a reciprocal process in which research and theory affect practice and the results and application in practice inform further research and is in itself a way of building theory. Nastasi et al. (1997) note that this approach to program development, implementation, and evaluation is consistent with most school psychologist practitioners' training as scientist-practitioners and offers a promising model for integrating the roles of school psychologists that sometimes appear disparate. "That is, an action research model provides the framework for integrating assessment, intervention, consultation, and research. Ideally, this integration also fosters engagement in and dissemination of research by practitioners" (p. 4). The work that a school psychologist has completed in literature review and investigating model programs and empirically supported interventions will provide a good working foundation for accomplishing this aspect of program development.

ECOLOGICAL-DEVELOPMENTAL MODEL

If a program is to be exemplary, then it is vital that the program meet the needs of the system and the needs of the individuals within the system. In the ecological-developmental model, development is considered to be a progressive and mutual adaptation of the environment and of the individual. Nastasi et al. (1997) states, "... in order to understand and/or change human behavior, one must attend to the ecological contexts in which the individual is socialized (e.g., school, family, community) as well as the interaction of those contexts (e.g. parent-teacher interaction). Furthermore, the individual plays an active role in development, such that one's personal qualities and behavior engender certain interactions with the environment" (p. 5). The background work that the school psychologist has done in systems analysis and needs assessment as described earlier in this chapter should provide a good foundation for looking into these reciprocal factors in program development, implementation, and evaluation. Look carefully at points of interaction and reciprocal influence in the context of the program and services.

COLLABORATIVE/PARTICIPATORY MODEL

It is essential that the process of designing, implementing, and evaluating the program is a model of collaboration between the program planning team, stakeholder groups, and decision makers and that each of these groups is involved as members of the team. This approach is consistent with school psychologists training in collaborative consultation and problem solving, applied here to a system. This model is also consistent with school reform efforts and best practice with regard to coordinated and integrated service delivery. Collaboration and coalition building is not easy due to inevitable conflicts in different organizations' conceptualization of their roles, conflicts about professional turf issues, potential competition for funding, and other more personal power and control issues. However, without these potentially political negotiations, comprehensive and coordinated services for students and their families will not occur. Adelman (1996) and Knoff (1996) suggest that school psychologists are possible organizational facilitators who can coordinate collaboration across agencies and between schools, families, and community agencies. These collaborative efforts and participatory management approaches are likely to ensure that the program attends to cultural factors, empowers members of stakeholder groups, and facilitates the process of institutionalizing the program (Nastasi et al., 1997).

CONTINUUM OF SERVICES

Comprehensive and coordinated mental health services require a broad-based model ranging from prevention programs targeted to the regular classroom to treatment services for individuals with moderate to severe mental health problems. The services vary on a continuum across several factors including population served, referral processes, context for service provision, and staffing requirements. Nastasi et al. (1997) propose four levels of intervention: prevention, risk reduction, early intervention, and treatment:

Level I : Prevention. Prevention services are targeted toward the general populations. They focus on fostering individual development and creating supportive social environments. All students receive this level of intervention that is delivered in the context of an intact group such as the classroom. Examples of these kinds of services include those in which personal-social goals regarding issues such as substance abuse are integrated into the academic curriculum.

Level II: Risk Reduction. Risk reduction services are targeted toward high risk population. These services focus on building competence, teaching coping skills, and modifying social context in which risky behaviors might occur. Students might self-select into this level of service delivery, which would typically be delivered in the context of a small group. An example of this level of service might include support groups for children of alcoholics.

Level III: Early Interventions. Early intervention services are targeted toward individuals with mild adjustment problems and are designed to treat mild adjustment problems, reduce the risk of more severe problems, and modify the context in which the problem behaviors manifest themselves to affect individual adjustment. Students might be referred for early intervention services though screening and/or referral. Services are typically delivered in individual or small group formats. An example of early intervention service is a counseling group for students experiencing mild depression.

Level IV: Treatment. This most intensive level of service delivery targets individuals with moderate to severe emotional disturbance and/or mental health needs. Service focuses on treating identified mental health problems and modifying context to effect the individual's functioning. Students would likely be referred and selected for this level of service through diagnosis by a mental health professional. Direct services are typically delivered in individual or small group contexts by mental health professionals.

MODEL OF EVALUATION

Program evaluation is a critical component of mental health services and programs delivered in school settings, which too often is not thoughtfully integrated into program development from the beginning. As illustrated earlier in the discussion about integrating theory, research, and practice, data from program evaluation informs both practice and theory and offers a defensible rationale for program implementation. Nastasi asserts that in order for program evaluation to be complete enough to assess key factors in service delivery and to inform practice, three key elements of program evaluation need to be included in the process.

The first is *acceptability*, which considers the participants' (both recipients and facilitators) perceptions and attitudes about the program's feasibility, efficacy, usefulness, and whether or not the program is consistent with their own world views. Examples of methods for assessing program acceptability include interviews, focus groups, questionnaires, and examining journals.

The second component is *integrity*, which looks at whether or not the program is implemented as designed. One component of this would be to document variations in program implementation by different facilitators or with various recipients to identify modifications needed in how the program is delivered or to address staff development and training issues. Examples of techniques to assess program integrity would be activity logs, observations, interviews, self-evaluation measures, and journals.

The third component is program *efficacy*, which examines program outcomes. This aspect of program evaluation measures the extent to which the program and services meet their stated goals and objectives. It also evaluates unintended program outcomes. Measures of program efficacy might include observation, interviews, self-report measures, rating scales, analog measures, and curriculum-based evaluation measures.

Choose Well-Documented Models and Empirically Validated Interventions

After completing the literature review and examination of programs during the preparation described earlier in this chapter, it is important to carefully examine the models available keeping two important factors in mind. First, is the information provided in light of the proposed model program's outcome and other evaluation data of high quality? Does the program provide outcome data and information about consumer satisfaction? Second, look at the match between your community and the students you serve and the demographic and organizational data reported by the programs you are investigating. There does not have to be a match, but sometimes settings and resources available can have an impact on program outcomes and consumers' perceptions of the efficacy of the program (Pluymert, 2000). A carefully chosen program model with a proven track record assists the practitioner in that the model is defensible on the basis of a track record of research. Practitioners will want to talk with individuals who are implementing the program and with the program originator or author, if possible. The advice and mentoring available in consulting with other professionals who are already immersed in the program that is under consideration can be a tremendous asset to a practitioner who is learning a new set of skills.

Legal Considerations

It is important to implement best legal practices when developing a mental health program in the school setting. Several aspects of law need to be carefully attended to including confidentiality, consent, and, when including students under entitlement provisions, IDEA regulations. It is also important to investigate state law and regulations with regard to mental health services, because consent and confidentiality in matters of mental health services are often different from those within IDEA and other applicable regulations.

Evans (1999) offers a review of the various aspects of consent for school-based mental health services. Consent is sometimes interpreted within the school setting as passive consent. In other words, parents are informed that they have access to information about mental health services and the fact that they have the right to object if they choose to do so. This is often the mechanism that is used for sex education and some prevention programs offered in the school setting. However, it may be best practice to take a more conservative approach and to obtain parental consent for students who will be receiving mental health services at school. Evans argues that there is a significant difference in the concept of consent for a school versus a clinic setting for mental health services. Parents do not send their children to school with the expectation that they will be receiving mental health services. Informed consent is important to protect the rights of the child, the parent, and the practitioner. Without parental consent, Evans warns, the practitioner is exposed to considerable potential liability.

The issue of confidentiality in school-based mental health services should be dealt with carefully in light of professional responsibilities such as duty to warn, typically confronting the school psychologist in the delivery of any mental health services in school settings. A confounding factor for confidentiality emerges because there is increasing collaboration between agencies and professionals to provide mental health services. Finally, as funding sources such as Medicaid and managed care companies become involved in school-based mental health services provisions, confidentiality becomes a consideration with regard to caps on a student's available future coverage, given services that might be provided in the school setting.

Finally, there are several aspects of IDEA that the practitioner needs to keep in mind when developing mental health services in the schools. Schacht and Hanson (1999) provide an overview of case law from across the country that highlights some of the legal aspects of school-based mental health services under IDEA. The authors highlight factors that have an impact on the development of programs and services, including the difference between a student having a DSM-IV diagnosis and the presence of a disability, the difference between incidents of student misconduct and the presence of a disability, least restrictive environments for service delivery, and mental health services as a related service for students who are entitled to special education services.

Develop a Blended Funding Base

One of the factors that contributes more than almost any other factor in the demise of mental health services and programs is discontinuation of the funding source. While school administrators value school-based mental health services, they are generally not equally enthusiastic about the school's responsibility for providing those services (Pluymert, 2000). If a program is going to go the distance over time in serving students and the school community, then it is important to look to a variety of funding sources for the program. There are many sources to investigate for funding mental health programs.

Nastasi et al. (1997) found the following funding patterns among the 103 programs included in the study:

1. 56% of the programs relied on multiple funding sources

2. 52% of the programs received funding from external grants

3. 64% of the programs were funded by schools, with 37% of these using special education funds and 32% funded as non–special education support services

4. 23% relied on Medicaid funds

5. 11% received funds from health insurance companies or HMO's, and 7% were linked to school-based health clinics.

6. 11% were funded by private agencies

7. 37% of the programs relied on some other source of funds

Several of the programs were volunteer efforts under the leadership of school psychologists, and one school psychologist stated that she personally "scrounged for funds." An interesting resource for the practitioner is a book written by a school administrator that retells her experiences in establishing school-based mental health services in her community (Hoover & Achilles, 1996).

Grant dollars through federal agencies, private industry or foundations are a good source of funding, but can also be risky over time as a program that depends heavily on grant monies can be devastated if the grant dollars are time-limited or dependent on the will of federal or state legislators. There are publications and on-line resources available to investigate grant possibilities, but the practitioner needs to be careful to use grant funding in conjunction with other more stable funding sources. Collaboration with other mental health agencies and with community and with parent groups can be a helpful source of both financial and human resources.

Sometimes the most valuable commodity is not dollars, but committed volunteers who receive support and training through the mental health professionals in the program. The inclusion of volunteer support is a good use of resources and also builds a sense of ownership that is an important factor in the institutionalization process. This concept can also be extended to in-kind donations of materials, space, and services that can be obtained from individuals, small businesses, and agencies.

Use Program Evaluation Data to Maximize Benefits to the Program

It is critical to complete program evaluation and to make the results of the program evaluation useful information for further program development, providing information about the program to constituent groups. Program evaluation is an important part of the school psychologist's role as scientist-practitioner, gathering and utilizing data to validate and potentially improve services. These are practices that may not be considered a priority in the light of the urgent matters of daily practice, but they are critical elements in best practice and in the program's ability to provide accountability and to promote its good work to the community.

Nastasi et al. (1997) found that of the 103 programs, most addressed program acceptability (79%), program integrity (66%), and program efficacy (80%). Forty-three percent reported that they conducted follow-up evaluations. Only 42% reported having any results available in writing, and only a handful of these programs actually provided written data after repeated requests.

The importance of program evaluation from a theoretical and program improvement perspective is clear. Without collecting data in a systematic fashion as was discussed earlier, the practitioner is reliant upon making decisions about services for children and youth absent any reliable benchmarks. There is a changing paradigm for service delivery in school psychology such that practitioners are increasingly utilizing resources such as curriculum-based evaluation (Howell & Nolet, 2000) for assessing and creating interventions for social behaviors. As this level of accountability becomes the standard for educational and psychological service delivery to individuals in the schools, mental health services and programs should be held to the same standard.

Program evaluation is not only required from a professional best practice standard, but funding sources and constituent support also call for the practitioner to produce data that demonstrate the efficacy of the program. Much of the excitement and good will generated around the creation of a program can be sustained through the use of data that demonstrate the positive outcomes of the program to the benefit of the community. Many of the communications activities described earlier, such as letters and presentations to community groups and decision makers, reports to constituent groups, articles written for local publications, and press releases, are good mechanisms for spreading the good word about the value of the program, as well as generating interest and support in the community for the important work of the program.

SUMMARY

The need for school-based mental health services has become increasingly apparent in recent years. School psychologists can be an outstanding resource to the school community in the development of effective mental health services to address the needs of students and families that they serve. From the perspective of both child and professional advocacy, it is vital that school psychologists become proactive in promoting their role as mental health service providers and in the development of exemplary mental health programs in schools.

Before a school psychologist can begin to develop a school-based mental health program, there are a number of factors that the practitioner needs to be cognizant of to maximize the likelihood of the long-term success of a program and to minimize frustration and roadblocks to the process. To have the opportunity to develop mental health programming in the school, many practitioners will find that their first priority is to build a foundation of credibility and trust within the district by providing excellent services in the day-to-day events and the crises that occur, and by promoting the value of the work they do through the use of communications activities. A second key to developing a successful mental health program is knowing how the school functions as a system and understanding its unique needs. The school psychologist will need to utilize systems consultation and needs assessment skills to serve as a catalyst for change. Third, the practitioner will need to actively build coalitions and networks for comprehensive and coordinated service delivery options. In addition, the school psychologist will need to become well prepared to plan, implement, and evaluate the service and/or program through research of the literature and a review of empirically supported interventions and existing program models that are well supported and show evidence of positive outcomes for students. If the practitioner attends to each of these factors, then the program has a much greater chance of institutionalization.

When the school psychologist is ready to approach program development, implementation, and evaluation, specific factors should be considered to facilitate the success of the program. Characteristics of exemplary mental health programs are incorporated in the program including theory-research-practice integration; an ecological-developmental approach; collaborative-participatory model; the provision of a continuum of mental health services; program evaluation that addresses program acceptability, integrity and efficacy; and the involvement of a school psychologist. Finally, the practitioner needs to ensure that exemplary programs attend to best practices in program development, implementation, and evaluation including choosing well-documented models and/or empirically validated interventions; giving close attention to legal considerations; developing a blended funding base; and completing program evaluation, utilizing the data to further develop the program and to promote it in the school community.

ANNOTATED BIBLIOGRAPHY

Goldman, R. (Ed.). (1997). Model mental health programs and educational reform [Special issue]. *American Journal of Orthopsychiatry, 67*(3).

This special issue provides an excellent overview of school-based mental health services. There are articles on the history of school-based mental health services, on theoretical approaches to school reform and mental health services, and several practical examples of programs including wraparound services and consultative service delivery by mental health professionals.

Nastasi, B. (Ed). (1998) Mental health services in the schools [Special issue]. *School Psychology Review, 27*(2). This issue focuses on school-based and school-linked mental health services. The articles discuss the role of school psychologists in mental health programs and provide several examples of model mental health programs in schools.

Psychology in the Schools. (2000). *37*(1). This journal provides a focus on the future of school based practice with a focus on mental health services including articles on the future of the profession of school psychology, the effect of violence on mental health services in the schools, and other thought-provoking articles by well-known authors in the field of school psychology.

Weist, M. (Ed.). (1999) Challenges and opportunities in expanded school mental health [Special issue]. *Clinical Psychology Review, 19*(2). This clinical psychology journal presents several articles that provide the practitioner with information about topics in the development of school-based mental health services including articles about policy issues, legal matters, psychologists working with primary care providers as partners in health-care provision, working with managed care companies, and the growing interface between education and mental health professionals in schools, including a discussion of turf issues.

62 Best Practices in School Discipline

OVERVIEW

Throughout the history of American education, school discipline has remained a primary concern among educators and the general public. As seen in the 32nd annual Phi Delta Kappa/Gallup Poll of the Public's Attitudes Toward the Public Schools (Rose & Gallup, 2000), a general "lack of discipline" is viewed by the public as the second biggest problem in public schools. "Fighting/violence/gangs," which are more specific and serious forms of discipline problems, are viewed as the fourth biggest problem. The 2000 poll also found that the public believes that the foremost purpose of public schools is "to prepare people to become responsible citizens." Although participants were not asked how educators could best achieve this goal, they were asked if they supported the use of harsh measures for those who fail to act responsibly, specifically in cases involving weapons. Results showed that 87% favor zero tolerance policies in schools.

The above results illustrate the conflicting views that parents and educators have had of school discipline over the years. That is, they have always recognized that the primary aim of education is to develop responsible citizenship, or self-discipline. At the same time, however, they have strongly supported the external use of discipline in order to maintain school environments that are safe, orderly, and conducive to learning. Over the course of American history various strategies and programs, both effective and ineffective, have been used in attempts to achieve both of these aims. Indeed, as seen below, many of the strategies used in the past to promote self-discipline and to maintain order and safety remain popular today. Thus, as one should expect, many of the debates and controversies over their use are not new to education, or to school psychology. This would include debates and controversies over corporal punishment, suspension, expulsion, the systematic use of extrinsic rewards, the placement of disruptive students in alternative education and special education settings, and the effectiveness of strategies and programs designed to promote social and emotional development.

A Brief History of School Discipline: The Shifting Importance of Prevention, Correction, and Remediation

Before the twentieth century, it was believed that self-discipline was best learned through the memorization of moral teachings based primarily on the Bible (McClellan, 1999). In addition to moral knowledge, parents and teachers strove to instill in children a fear of punishment and sense of shame for their wrongdoings. Such fear and shame were often justified, as harsh consequences, especially corporal punishment and public humiliation, were frequently used to teach self-discipline and maintain classroom order. The popularity of punitive techniques was perhaps best captured in Horace Mann's comment that "adults thought of punishment lightly, spoke of it with amusement, and inflicted it liberally" (as cited in Raichle, 1977/1978).

Strategies changed markedly in the early twentieth century. The use of physical punishment and teaching of Biblical scripture declined as a result of improved teacher training, increased national awareness of children's mental health needs, widespread public concern about the moral decay of the nation, and legal challenges (McClellan, 1999). The emphasis on threats, punishment, and religious education was replaced by an emphasis on democratic values, beliefs, and behaviors. The goal of this movement, known as character education, was to promote the growth of the ideal American citizen. Initially, this goal was advanced through direct teaching strategies. For example, teachers continued to depend on moral exhortations and teaching students to memorize what was "right" and "wrong." Instead of Biblical verses, however, children were taught to memorize oaths, codes of conduct, and passages that focused on qualities of moral character. In time, these direct strategies were replaced by more indirect ones. For example, classroom discussions and the active involvement of students in clubs and cooperative learning activities became common strategies for teaching self-discipline. It was believed that honesty, industry, responsibility, respect, moral decision making, and similar character traits were better learned through experience and practice than through memorization. Perhaps more important, it was believed that systematic efforts to teach such traits and values could *prevent* behavior problems, foster self-discipline, and thus allow teachers to devote less time to the correction of misbehavior. By 1935, every state required the teaching of character education (McKown, 1935).

As the emphasis on character education increased, the emphasis on harsh punitive strategies decreased. In particular, educators began to closely examine alternatives to corporal punishment. Behavioral strategies such as time-out and reinforcement of good behavior were used for correcting minor misbehavior, whereas exclusionary strategies such as suspension and expulsion were used for more serious and chronic misbehavior. Schools also began to understand the need for alternative programs that provided a greater range and intensity of mental health and remedial services. As a result, alternative schools for students with serious behavior problems began to appear (McClellan, 1999).

Thus, for almost a century, schools in America have recognized that school discipline should include more than the correction of everyday behavior problems in the classroom. To be sure, the *correction* of behavior problems continues to be an important component of school discipline, but as recognized by educators in the early 1900s, comprehensive school discipline should include two additional components: *prevention* and *remediation and crisis response*. Whereas the former involves all children, the latter targets those children who exhibit the most serious and chronic behavior problems. What has changed most over the years has been the relative emphasis placed on each of these components and the strategies associated with them. For example, as noted above, correction via fear and punishment was popular at the turn of the twentieth century and prevention via multiple methods of character education was popular in the early and mid twentieth century. Since then, the popularity of a kaleidoscope of program models that employ a variety of preventive and corrective strategies has waxed and waned, including models that focus on values and emotional well-being (e.g., Values Clarification; Raths, Harmin, & Simon, 1966), moral reasoning and social decision making (e.g., the Cognitive-Developmental Approach; Kohlberg, 1981), interpersonal communication (e.g., Teacher Effectiveness Training; Gordon, 1974), social problem solving (Shure, 1992), responsibility (e.g., Reality Therapy; Glasser, 1992), and behavior modification (e.g., Assertive Discipline; Canter & Canter, 1992).

There is little research supporting the above models, as well as other models of school discipline that emphasize a single dimension . However, research does support many of the *strategies* used in these models (Bear, 1998). Indeed, research indicates that multiple strategies are needed to promote responsible behavior and that these strategies must target how children *think*, *feel*, and *act* (Zins, Elias, Greenberg, & Weissberg, 2000). Fortunately, there is a wealth of such strategies from which school psychologists can draw when developing and implementing comprehensive school-based programs for preventing, correcting, and remediating school discipline problems.

School Discipline Today: A Return to Fear and Punishment?

Recently, there has been a shift in emphasis from preventing and correcting school discipline problems to remediating and responding to serious discipline problems. In response to fears among legislators and the general public that school violence has increased in recent years (Skiba & Peterson, 1999), crisis response teams have been created and inservice trainings have been held on how school professionals can respond to violent acts. In addition, zero tolerance policies have become increasingly popular, with student misbehavior often resulting in the automatic application of harsh disciplinary consequences such as suspension, expulsion, and placement in alternative school programs. Moreover, rather than preventing behavior problems by promoting the social, emotional, and moral development of children, many schools have elected to "prevent" behavior problems by focusing on the systematic control of environmental factors perceived to be the primary antecedents of discipline problems. That is, many schools have focused primarily on the purchase of increased security measures, the hiring of police (or school resource officers), and the issuing of staff and student identification badges (Skiba & Peterson, 1999). Such strategies, which also characterize prisons, have received little or no empirical support in the schools (Hyman & Perone, 1998), especially with respect to preventing school violence and promoting socially responsible behavior.

Clearly, acts of violence should not be tolerated: Responding to and remediating serious behavior problems *should* be a priority among those schools in which violence is a problem. Contrary to the perceptions of many parents and educators, however, such schools are rare (Hyman & Perone, 1998; Skiba & Peterson, 1999), especially when "school violence" is appropriately defined as serious (i.e., typically criminal) acts of aggression and not milder forms of verbal and physical aggression (e.g., teasing, bullying, and rejecting others). Although the latter behaviors are relatively normative, the former are fairly uncommon. That is, the majority of schools (90%) report no serious violent crimes (i.e., physical attack or fight with a weapon, robbery, murder, rape, or sexual battery; U.S. Department of Education, 1999), and the majority of students (99%) commit no serious violent crimes, at least not at school (National Center for Education Statistics, 1998). Given these statistics, the great amount of emphasis placed on responses to violence is unwarranted in the vast majority of schools. To be sure, efforts to target violence should be one aspect of a school's discipline plan—a plan that should balance all three necessary components. As discussed below, however, it is unlikely that strategies and programs that focus exclusively on reducing school violence will be effective in developing self-discipline and preventing everyday behavior problems, or in creating a positive atmosphere that is conducive to learning.

BASIC CONSIDERATIONS

There are few topics in school psychology that require a broader base of knowledge and skills than that of school discipline, especially when the components of prevention, correction, and remediation are emphasized. Of particular importance to school psychologists is an understanding of the multiple risk and protective factors related to social and emotional adjustment or maladjustment. These include biological and temperamental factors, social, emotional, and academic competencies, teacher-student relations, family functioning, parenting skills and practices, peer associations, school climate and classroom management strategies, and community factors. Such factors influence behavior in a complex, reciprocal, and cumulative fashion. For example, a student who lacks social-emotional competencies and social skills or whose temperament is characterized by hyperactivity, impulsivity, and inattentiveness will be more difficult to teach. In turn, the student is more likely to be subject to harsh and punitive discipline, especially when placed with a teacher who lacks patience, tolerance, and behavior management skills or who lacks the resources that might be necessary to accommodate the student in a class with many other at-risk students. A teacher's punishment-oriented style toward discipline not only fails to promote social-emotional competencies and prosocial behavior in the student, but also provides negative models of behavior, thereby further impeding the student's social and emotional development. The risk for disciplinary problems is even greater when the child experiences academic failure and the lack of family support. Peer rejection and eventual drift toward a deviant peer group often evolve, as well as the risk of other indicators of social and emotional maladjustment, including low self-esteem and criminality (Kupersmidt, Coie, & Dodge, 1990).

A developmental, multi-risk factor view of conduct problems has profound implications for the prevention, correction, and remediation components of school discipline programs. In particular, it highlights the need for each component to address multiple risk and protective factors. It also suggests why past and present programs focusing on only one aspect of behavior (e.g., self-esteem, social problem solving, communication skills, social skills) fail.

In addition to knowledge of multiple risk and protective factors, it is critical that school psychologists possess knowledge and skills in a variety of areas of psychology and education, including problem-solving consultation, classroom management, character education, systems change, applied behavior analysis, behavior therapy, individual and group counseling, parent education, and crisis intervention. General knowledge of children's social, emotional, and moral development also is important, as is knowledge in the more specific areas of socialization, child rearing, self-regulation, internalization, aggression, and juvenile delinquency. Of central importance to the implementation of strategies and programs that draw from the above skills and knowledge is the evaluation of their effectiveness. That is, school psychologists should play a pivotal role not only in guiding schools in the implementation of empirically based strategies and programs, but also in demonstrating whether or not such strategies and programs result in positive short- and long-term outcomes.

Furthermore, given that school discipline has increasingly become the focus of legal challenges and legislative acts, school psychologists must keep abreast in these areas. In particular, they should be aware of current state and federal regulations, case law, and other court rulings regarding provisions in Section 504 of the Rehabilitation Act and in the 1997 amendments to the Individuals with Disabilities Education Act (IDEA) that focus on school discipline and children with disabilities. These provisions should serve as an impetus for school psychologists to reflect upon the preventive, corrective, and remedial components of their schools' discipline policies and practices.

BEST PRACTICES

In this section we highlight school discipline strategies that characterize programs and models of demonstrated effectiveness. It is important to note that although the strategies are grouped under the categories of prevention, correction, and remediation, few strategies are specific to one category. Our dividing lines between categories of disciplinary strategies are somewhat arbitrary. Undoubtedly, the corrective component would include preventive strategies and the remediation component would incorporate both preventive and corrective strategies. As educational intervention research continues to inform practice, it has become increasingly clear that the most effective learning environments are those in which there is a planful, consistent, seamless, and data-based approach to the prevention, correction, and remediation of disciplinary problems. Our separation of these sections is therefore based more on relative emphases than on exclusive distinctions.

Best Practices for Promoting Self-Discipline and Preventing Discipline Problems

Most authorities on the topic of school discipline agree that prevention should be the primary focus of a school's comprehensive discipline plan. This is for good reason. As noted by Walker, Colvin, and Ramsey (1995), when implemented successfully, comprehensive prevention programs solve the adjustment problems of 75–85% of a school's students and they do so in a cost effective manner, costing approximately $5–20 per student compared to at least $25,000 per student for intensive remediation or treatment programs. Preventive programs target all children, employing a variety of strategies designed to achieve two interrelated goals: (a) the development of self-discipline and (b) the establishment and maintenance of school atmospheres that encourage prosocial behavior and inhibit disciplinary problems. These strategies often serve to promote not only appropriate classroom behavior but also academic achievement and interpersonal relationships (Zins et al., 2000).

Self-discipline entails self-directed inhibition of antisocial behavior, assuming responsibility for one's actions, understanding of right from wrong, and an appreciation of the importance of cooperative relationships in the classroom and society. Self-discipline reflects internalization, which is defined as "taking over the values and attitudes of society as one's own so that socially acceptable behavior is motivated not by anticipation of external consequences but by intrinsic or internal factors" (Grusec & Goodnow, 1994, p. 4). As such, self-discipline is most evident when one acts prosocially and inhibits antisocial behavior in the absence of external regulators of behavior, such as the presence of adults. The development of self-discipline, rather than the external control of behavior, should be the long-term goal of all schools.

SCHOOL-WIDE AND CLASSROOM STRATEGIES

Several decades of research on school and teacher effectiveness have resulted in the identification of a variety of classroom and school-wide strategies for developing self-discipline and preventing behavior problems (Bear, 1998; Good & Brophy, 2000; Grusec & Goodnow, 1994). A summary of recommendations based on this research appears in Table 1.

SKILLS AND DISPOSITIONS OF EFFECTIVE TEACHERS

The classroom management strategies listed in Table 1 characterize teachers who are "authoritative" in their approach to school discipline (Brophy, 1996).

Table 1. Recommended school-based strategies for developing self-discipline and preventing behavior problems

School-wide strategies

- Develop a commitment on the part of all teachers, administrators, and support staff to work together to improve school discipline and promote a positive school climate.
- In collaboration with teachers, students, parents, and other members of the school community develop and consistently enforce clear and fair rules and sanctions for problem behaviors. Rules should be incorporated into written policies that are distributed to all involved parties.
- Set high, yet realistic, academic and behavioral expectations and communicate that such expectations, and accountability for meeting them, should be shared by students, teachers, and parents alike.
- Implement curricula and school-wide activities designed to promote social and emotional learning. This may include lessons embedded within the general curriculum that highlight prosocial and democratic values such as responsibility and respect for others; lessons designed to teach social problem solving and social decision-making skills; and school-wide assemblies that recognize prosocial behavior and convey prosocial values.
- Ensure that physical facilities are well designed and monitored. Increase supervision of children where behavior problems most often occur (e.g., halls, playground, cafeteria).
- Provide ongoing staff development and supervision.
- Make sure that program components are being implemented with fidelity and are being evaluated as to their acceptability and effectiveness.

Classroom strategies

- Adopt classroom management and disciplinary practices that combine proactive, instructive, and corrective strategies. That is, make sure that teachers work hard to prevent misbehaviors before they occur, emphasize self-discipline (as opposed to external control), and correct behavior problems fairly and consistently.
- Arrange the physical environment of each classroom in ways that reduce congestion and facilitate the smooth and quiet movement of students.
- Beginning with the first week of school, establish clear and predictable routines and actively involve students in the establishment of rules and consequences.
- Reinforce appropriate behavior ("catch 'em being good") and emphasize internal attributions (i.e., focusing students' attention on the internal, rather than external, reasons for their behavior).
- Frequently discuss rules and behaviors with students so they not only recognize what behaviors are "right" and "wrong" but also understand why. Such discussions are particularly effective if they use inductions (i.e., focusing students' attention on the effects of their behavior on others instead of on external consequences).
- Prevent boredom and frustration by employing a variety of teaching methods, developmentally appropriate and motivating materials, and curriculum materials and instructions that are adapted to the needs, interests, and abilities of individual students.
- Promote cooperation among students rather than competition.
- Offer opportunities for students to voice their needs and opinions (e.g., class meetings, student councils) and to solve social problems on their own.

Authoritative teachers set high standards and hold high expectations, enforce rules and standards in a firm, fair, and consistent manner, and promote autonomy by encouraging children's active participation in decisions regarding their behavior (Bear, 1998). Authoritative teachers emphasize strategies that are proactive (i.e., focus on the antecedents of behavior), rather than relying solely upon strategies that are reactive (i.e., focus on the consequences of behavior). Their use of positive, proactive discipline techniques, in combination with more punitive, reactive strategies (when needed), increases the likelihood that students will exhibit appropriate behavior willingly rather than grudgingly (Brophy, 1996).

Another important characteristic of authoritative teachers is that they tend to display warmth and acceptance toward their students (Brophy, 1996). Warmth may be communicated by expressing positive affect, sympathy, and support toward students, as well as interest in each student as a person and enjoyment of each student's company. Decades of research have demonstrated that students tend to internalize the values and standards of adults with whom they share warm relationships. Their compliance may initially be motivated by a desire to either imitate or please the adults, but tends to become more internally motivated over time (Hoffman, 2000). In addition to fostering internalization, communication of warmth may facilitate the development of close, supportive relationships between teachers and students, which in turn have been linked with decreased drop-out, risk-taking, and aggression, as well as increased academic and social competence (see Pianta, 1999, for a review). Like warmth, acceptance is delivered non-contingently and thus is not conditional upon students' behavior. Acceptance may be communicated when teachers draw a distinction between students and their misbehavior, adopt an attitude that "everyday is a new day" by not holding students' previous discipline problems against them, and consider several possible explanations for students' behavior rather than automatically assuming negative intentions (Brophy, 1996). Together, warmth and acceptance tend to form the basis for teacher-student relationships characterized by mutual respect, thus motivating students to comply with teachers out of respect for them rather than out of fear or mere obedience.

Not only do effective teachers strive to develop positive relationships with the students in their classrooms, but they also seek to promote positive relationships and a sense of community among the students themselves. By emphasizing cooperative rather than competitive activities, teachers communicate the idea that the classroom is a community in which students can help, rather than hinder, each other's success. Responsibility for classroom behavior is shared by encouraging students to take others' feelings and perspectives into account; by doing so, teachers foster feelings of empathy and guilt, thereby motivating students to engage in prosocial rather than antisocial behavior (Eisenberg & Fabes, 1997). In addition, their efforts to build a caring classroom community promote a sense of belonging among students and a sense of attachment to school, both of which may reduce students' sense of alienation and potential for violence (Walker et al., 1995). Finally, effective teachers regularly and unobtrusively measure and evaluate the effects of their efforts on students' prosocial and antisocial behaviors. In sum, effective teachers create a classroom climate in which their students follow norms for appropriate behavior, not only out of respect for the teacher but also out of respect for one another.

STRATEGIES AND PROGRAMS FOR DEVELOPING RESPONSIBLE BEHAVIOR

In addition to identifying teacher characteristics associated with school discipline, a great deal of research in recent years has focused on individual child characteristics that might be targeted in the prevention of behavior problems and the development of responsible behavior. Of particular emphasis has been the identification of cognitions, emotions, and social skills that mediate social and emotional adjustment in the classroom. Considerable attention has been directed toward social information processing, social problem solving, or social decision-making skills, such as interpreting social cues, clarifying goals, generating solutions, evaluating and choosing solutions, and acting upon the solutions chosen (Crick & Dodge, 1994); anger management and impulse control (Lochman, Dunn, & Wagner, 1997); moral reasoning (Bear, Richards, & Gibbs, 1997); social perspective taking, interpersonal understanding, and negotiation strategies (Selman & Schultz, 1990); empathy (Eisenberg & Fabes, 1997); and self-management, including self-monitoring, self-evaluation, and self-reinforcement skills (Shapiro & Cole, 1994).

Given their roles in mediating classroom behavior, the above areas are routinely incorporated into curriculum packages and programs designed to promote self-discipline and to prevent disciplinary problems ranging from tardiness and classroom disruption to violent forms of aggression. Many of these packages and programs have been shown to be effective in improving social cognitive and emotional skills (Bear, Webster-Stratton, Furlong, & Rhee, 2000). Very few, however, meet the empirically rigorous standard of having demonstrated lasting effects on behavior. Three popular programs for which at least one study demonstrated improvements in behavior that were not simply short-term in duration are *BrainPower* (Hudley, 1999), *PATHS* (Greenberg, Kusche, Cook, & Quamma, 1995), and *Second Step* (Grossman et al., 1997). Note that each of these curriculum programs targets a combination of social, emotional, and behavioral skills.

Overall, research supports strategies that teach a combination of social cognitive, emotional, and behavioral skills. However, there is little, if any, empirical research supporting character education programs reminiscent of the nineteenth century that rely primarily on moral appeal, fear arousal, and information dissemination in teaching students *what* to think (as opposed to *how* to think or how to decide *why* certain actions are wrong; Gottfredson, 1997). Unfortunately, many programs that rely primarily on "lecturing" remain popular today. Included among these are deterrence programs such as Scared Straight and law-related education programs such as DARE (Drug Resistance Awareness Education; Gottfredson, 1997). (Note, however, that the curriculum for the DARE program has been revised recently to include social problem solving and resiliency strategies found to be effective in other programs.) Although widely used among school psychologists, programs that focus on the direct teaching of specific social skills also lack empirical support, especially with respect to lasting improvement in behavior (DuPaul & Eckert, 1994). Likewise, little research indicates that peer mediation programs and recreational programs produce changes in behavior that are maintained over time and that generalize across settings (Gottfredson, 1997). It should be noted, however, that such lack of evidence does not warrant the conclusion that the strategies emphasized in these programs are not valuable, but only that they are likely to be ineffective in achieving lasting improvement in behavior unless they are combined with other strategies.

Best Practices for Correcting Discipline Problems

Teachers are most likely to initiate corrective disciplinary measures when they perceive misbehavior as disrupting or threatening the order of a classroom activity or as endangering the student or others, especially if the behavior is highly visible and contagious. Such misbehavior typically includes noncompliance/defiance, tantrums, aggression, and property destruction (Marquis et al., 2000). The goals of corrective strategies are to terminate the problem behavior if it is presently occurring, weaken or eliminate the likelihood that the student will engage in that behavior again, and replace the behavior with more socially appropriate behavior. As mentioned earlier, many of the preventive strategies described above can, and *should*, be used, when correcting problem behavior. Indeed, incidents of behavior problems provide excellent opportunities for children to learn and practice the cognitive, emotional, and behavioral skills targeted in the prevention component. When correcting misbehavior, however, it often is necessary to strategically apply specific punishment and reinforcement strategies that have proven effective in reducing misbehavior (Martens, Witt, Daly, & Vollmer, 1999; Walker et al., 1995).

PUNISHMENT

No other topic has generated more controversy and debate among writers and authorities on school discipline than the use of punishment in the schools. Whereas few, if any, experts on school discipline disagree that developing self-discipline should be a primary aim of education, many question if the use of punishment helps to achieve this important goal. Over the years, many of the most popular writers on school discipline, including Glasser (1992), Gordon (1974), and Kohn (1996), have been quite strident in their opposition to punishment. But school administrators, teachers, parents, and legislators have been equally strident in demanding that "discipline problems" be controlled and not go unpunished (Skiba & Peterson, 1999). Support for punitive strategies continues for several reasons: They often result in immediate decreases in behavior, they are quick and easy to use, their use often is expected of teachers and school administrators, and they generate a sense of control, power, and justice among those who administer them (Kohn, 1996).

Technically speaking, punishment refers to the use of an unpleasant consequence to decrease the likelihood that the behavior of concern will occur in the future (Martens et al., 1999). Corporal punishment is the most commonly criticized form of punishment. Indeed, nearly all professional organizations in psychology and education, including the National Association of School Psychologists (NASP), advocate that corporal punishment be banned from the schools. Suspension and expulsion also have been the focus of much criticism. As true with punishment strategies in general, suspension and expulsion have many limitations. Among their limitations are that they (a) fail to address factors, including classroom and school factors, that underlie the student's problem behavior; (b) do not teach replacement behaviors; (c) produce only short-term, non-enduring, decreases in behavior problems; (d) are likely to be harmful to the student-teacher relationship; and (e) are likely to foster resentment, retaliation, and emotions that are counterproductive to learning. Moreover, suspension and expulsion often allow students to avoid or escape from situations they find aversive, such as academic work, peer rejection, and a harsh and non-caring teacher. As a result, their inappropriate behavior is negatively reinforced. These strategies also tend to result in the loss of valuable instructional time as well as in increased exposure to negative role models (Schloss & Smith, 1998).

Other punishment strategies include verbal reprimands, removal of privileges, time-out, over-correction, and response cost. These strategies are much less contentious than corporal punishment, expulsion, and suspension and are among the most popular disciplinary strategies used by teachers (Brophy, 1996). Although widely employed and effective in causing short-term decreases in behavior, they too share many of the limitations presented above. In light of these limitations, we do not recommend that punishment strategies necessarily be eliminated (except for corporal punishment) but rather that they be used only after less restrictive interventions have failed to reduce misbehavior. Moreover, it is recommended that when used, punishment strategies should always be combined with strategies for teaching and reinforcing appropriate behaviors (Brophy, 1996; Martens et al., 1999). Such an approach not only has an ethical basis, but also is supported by research.

POSITIVE BEHAVIORAL INTERVENTIONS FOR CORRECTING BEHAVIOR PROBLEMS

Positive reductive techniques. Although positive reinforcement is defined by its strengthening effect on a behavior, a variety of related techniques apply the principle of *positive* reinforcement, seemingly paradoxically, to reduce or eliminate misbehavior (Webber & Scheuermann, 1991). Positive reinforcement, such as privileges and social or material rewards, is used to reward a student when he or she (a) completely refrains from exhibiting a problem behavior during a specified interval of time (i.e., Differential Reinforcement of Other behaviors; DRO), (b) performs a specific appropriate behavior that is physically incompatible (i.e., mutually exclusive) with the problem behavior (i.e., Differential Reinforcement of Incompatible behaviors; DRI), (c) exercises sufficient control over a problem behavior, keeping its frequency under a preset limit during a specified interval of time (i.e., Differential Reinforcement of Lower rates of behavior; DRL), or (d) performs a specific appropriate behavior that achieves the same function for the student but is not physically incompatible with the problem behavior (i.e., Differential Reinforcement of Alternative behaviors; DRA). Because these procedures employ no aversive stimuli to achieve reduction of the problem behavior, they should be considered the first resort when a school psychologist is planning interventions to correct problem behaviors. Procedures such as DRI are especially valuable because they reduce the frequency of the problem behavior while simultaneously strengthening an appropriate replacement behavior.

Behavioral momentum. To correct noncompliance and defiance, teachers may issue a series of requests with which they know the student is likely to comply. For example, the requested activities may be reinforcing in and of themselves or the teacher may know, based on previous experience, that particular compliant responses have been reinforced in the past. Through this series of compliances, a *momentum* of compliance is built up such that, when the heretofore non-complied-with request is delivered, it has a much higher probability of success (Mace, 1996). Of course, as soon as the student complies with this target request, the student should be rewarded. Again, this behavior intervention strategy employs no aversive stimuli.

School-home contingency notes. As emphasized in the previous (and following) section, home-school collaboration greatly enhances the prospects that an intervention will be effective. A simple strategy for facilitating teacher-parent communication and improving student behavior involves the use of school-home contingency notes. The basic components involve a teacher periodically sending home a brief written report on a child's behavioral performance and a parent reviewing the report, delivering the prescribed consequences to the child, signing the report, and sending it back to the teacher. School-home notes have been described as "one of the most effective techniques for improving a student's motivation and classroom behavior. It also is one of the most mismanaged and underutilized techniques" (Jenson & Reavis, 1995, p. 29).

Group contingencies. Any of the basic behavior analytic intervention principles that are applied to individual students also can be applied to groups of students, including whole classes. Group contingencies tend to cluster into one of three broad categories based on the performance criterion in the contingency (Sulzer-Azaroff & Mayer, 1991). In *dependent group contingencies*, the reward (or punishment) of every student in the class depends on the performance of a selected subset of students. This technique should be considered only if the teacher is certain that peer support rather than peer pressure will be provided to the students in the targeted subset. In *independent group contingencies*, the reward (or punishment) of the student depends only on the performance of that student. The contingency is the same for all students but is applied individually. In *interdependent group contingencies*, the reward (or punishment) of any student in the class depends in some way on the performance of every member of the class. There is evidence that well-designed group contingencies and individual contingencies can achieve comparable reductions in problem behaviors (Sulzer-Azaroff & Mayer, 1991). Since group contingencies are often more efficient, they might be favored by teachers in busy situations.

Group contingency strategies often are used in various game formats. Such formats offer powerful motivational properties to suppress undesirable behaviors and strengthen socially valued behaviors within a positive or "fun" learning environment. Probably the earliest classroom motivational game format, and one of the most popular, is the interdependent group contingency called the Good Behavior Game (Barrish, Saunders, & Wolf, 1969). Although different variations of the game have been investigated, most share the following features: (a) specific classroom rules are listed, (b) the class is divided into two or more teams, (c) each team receives a mark on the scoreboard whenever a member of that team earns a point or breaks a rule during a lesson, and (d) the team(s) scoring points above (or below) a predetermined criterion number are awarded reinforcers (e.g., praise, extra recess, less homework, special status). In addition to being relatively simple to operate and effective when properly designed, the Good Behavior Game is viewed favorably by teachers (Tingstrom, 1994).

Self-management. In many respects, procedures to directly teach and strengthen students' self-management of their behaviors and skills represent the pinnacle of behavior analytic corrective procedures. Interestingly, they also may share more methodological details with cognitive approaches than any other behavior analytic procedure, though the differences in terminology are often pronounced. The objectives of these procedures are typically for students to successfully monitor their own behavior; evaluate the behavior with respect to some standard for appropriate behavior; if the behavior is deemed to be inappropriate, then cease it and replace it with an appropriate alternative; if the behavior is deemed to be appropriate, then maintain it and issue self-feedback and/or, at the proper time, self-rewards (Shapiro & Cole, 1994). The overall goal of self-management is for students to increasingly assume adult-like responsibility for their own proper demeanor by fluidly and seamlessly performing these steps as the situation warrants, thereby eliminating the need for external supervision of their behavior. In most training situations, self-recording is an important skill that is embedded between self-monitoring and self-evaluation. This permits students to become aware of the magnitude of their behavior problem and provides a basis for their objective evaluation of their progress. Self-management procedures have been evaluated across hundreds of empirical research investigations and represent powerful preventive and corrective intervention tools for school psychologists.

SELECTING AMONG CORRECTIVE STRATEGIES

Educational research has documented a large number of corrective strategies shown to be effective with some students in some settings under some circumstances (some of which are highlighted here). A school psychologist with knowledge and skills in these strategies might very well confront a dilemma in deciding *which* strategies are the most appropriate for the particular student of concern. Functional behavioral assessment and positive behavioral support provide the school psychologist well-studied principles and processes for making informed decisions resulting in effective interventions.

Functional behavioral assessment. Regardless whether punishment or reinforcement strategies are used to correct misbehavior, the strategies should be chosen on the basis of a functional behavioral assessment (FBA). As seen in the chapter on FBA in this volume, school psychologists can develop more effective and more durable interventions, and develop them more expeditiously, if they first acquire knowledge about the triggers and functions of the problem behaviors and then design the interventions to be responsive to those factors. This conception acknowledges two fundamental beliefs about the nature of problem behaviors: (a) a problem behavior does not occur in a vacuum (it is related to the *context* in which it occurs) and (b) a problem behavior serves some *function* for the student, which makes it logical and reasonable from the student's perspective. A recent large-scale meta-analysis revealed that interventions for problem behaviors were substantially more effective when a functional assessment was conducted first and the outcomes were used to design the intervention (Marquis et al., 2000). Furthermore, when surveyed, most practitioners rated functional assessment procedures as extremely or very useful (Desrochers, Hile, & Williams-Moseley, 1997).

Positive behavioral support. Concomitant with the heightened emphasis on conducting functional assessments, researchers have increasingly endorsed the design and implementation of interventions that provide the student *positive* behavioral support (PBS). This movement has been fueled largely by ethical concerns over the use of intrusive, restrictive, and punitive disciplinary measures and by research documenting negative effects that are frequently associated with their use (Donnellan, LaVigna, Negri-Shoultz, & Fassbender,, 1988). Positive behavioral support has been defined as "the application of behavioral principles within the context of community norms to reduce problem behaviors and build appropriate behaviors that result in durable behavior change" (Marquis et al., 2000, p. 138).

The large-scale meta-analysis by Marquis et al. (2000) showed that PBS interventions have been effective in reducing problem behaviors across a wide variety of student characteristics (including age, gender, degree of handicap, and diagnosis), problem behaviors (including self-injury, tantrums, aggression, and property destruction), and interventions. Also, the use of multi-component interventions to address both the triggers and the functions of a problem behavior appears to be more effective than the use of a single intervention. Their findings substantiate the results of another meta-analysis by Stage and Quiroz (1997), who also reported large effect sizes for behavior analytic interventions. Of the strategies that they studied, the three most effective on average were group contingencies, self-management, and positive-reductive differential reinforcement.

Four factors are responsible for the effectiveness and growing popularity of PBS approaches to disciplinary problems. First, when done well, they are comprehensive. Both the antecedents and the consequences of a problem behavior are addressed. For the first time in the development of the behavior analytic framework, however, the primary emphasis is on the former. In this approach, the antecedents include both non-school factors, such as negative family influences, deficient coping skills, and low self-esteem (sometimes referred to as setting events or slow triggers), and factors in the immediate school environment, such as teacher demands and student provocation. As noted by Marquis et al. (2000), "a key concept in PBS is that deficient contexts must be remediated first in order to reduce problem behavior" (p. 138). Second, after considering the findings of a functional assessment, the selection of an intervention should be guided by the principle of the *least restrictive alternative*. This means that the practitioner always should choose as a first resort the most appropriate intervention strategy that is the least restrictive on a student's personal freedom and the least intrusive on the student's personal space. A valuable aid to a school psychologist in making these selections is the hierarchical ordering of reductive strategies, from least to most restrictive (Schloss & Smith, 1998). Third, whenever interventions are designed to reduce or eliminate a student's problem behaviors, they also must include strategies to teach appropriate replacement behaviors. This serves not only to build the student's behavioral repertoire but also to facilitate the continued suppression of the problem behavior (Marquis et al., 2000). Fourth, prior to changing to a more restrictive, less positive intervention strategy in the hierarchy, a school psychologist first must be informed by data that show that the current intervention is not effective. Such practices are consistent with the behavior analytic tradition of using field data to substantiate clinical impressions and serves to safeguard the student against hasty decisions by interventionists to use more punitive interventions unnecessarily (Schloss & Smith, 1998).

Remediating, and Responding to, Chronic and Serious Behavior Problems

The above preventive and corrective strategies are sufficient for addressing the needs of the majority of children, but more comprehensive and intensive services are necessary for the children who (a) exhibit behavior problems that are chronic and resistant to common classroom-based interventions and (b) exhibit behaviors, irrespective of chronicity, that are of serious harm, or threat thereof, to self and others. Included would be the estimated 2–9% of children whose behavior warrants the diagnosis of conduct disorder and the estimated 6–10% whose behavior warrants the diagnosis of oppositional defiant disorder (McMahon & Wells, 1998). Also included would be children who are targeted in the disciplinary provisions of the 1997 amendments to IDEA, which pertain to cases involving possession of a weapon or illegal drugs, or cases in which the child is determined by an hearing officer to be "substantially likely" to injure self or others.

GENERAL CHARACTERISTICS OF EFFECTIVE REMEDIAL PROGRAMS

There is a wealth of research on the effectiveness of various interventions for children with conduct disorders, including those who exhibit violent behavior. Effective programs tend to share certain characteristics (Bear et al., 2000). In general, they are:

1. *Comprehensive*, targeting multiple risk and protective factors

2. *Broad-based*, adopting a systems perspective in which schools, families, agencies, and communities work together in preventing and treating antisocial and aggressive behavior

3. *Guided by theory and research*, using interventions that are conceptually and empirically justified

4. *Intensive and sustained over time*, with a commitment to providing adequate resources

5. *Sensitive to* developmental differences in behavior, the determinants of behavior, and the appropriateness of interventions

6. *Cognizant of the importance of early intervention*. This would include interventions provided at an early age, as well as interventions that are provided when indicators of behavior problems first appear

In particular, there is growing evidence that a parent or family component to intervention is critical to produce lasting improvements in behavior. In combination with parent management training or family therapy, or when these services are not feasible, home-school collaboration and consultation should be provided.

CRISIS INTERVENTION

In light of school shootings that have plagued the nation, the responses that schools and communities make to crises are now recognized as critical components of intervention. Readers are referred to two free documents produced by the U.S. Department of Education in collaboration with NASP and the Center for Effective Collaboration and Practice: *Early Warning, Timely Response: A Guide to Safe Schools* (Dwyer, Osher, & Warger, 1998) and *Safeguarding Our Children: An Action Guide* (Dwyer & Osher, 2000), for useful guidelines and recommendations in developing crisis response teams and in responding to crises.

ALTERNATIVE EDUCATION PROGRAMS

The rapid growth in alternative education programs across the nation can largely be attributed to the widespread adoption of zero tolerance policies and to the new provisions in IDEA that stipulate that children with disabilities be placed into an interim alternative educational setting, with or without parent permission, for certain disciplinary infractions. It is beyond the scope of this chapter to review federal regulations that govern when children with disabilities may be placed into such settings or to review related issues and concepts (e.g., manifestation determination). School psychologists are referred to other resources, including the chapter in this volume on Functional Behavioral Assessment and several recent publications by NASP (see Bear, Quinn, & Burkholder, 2001; Telzrow & Tankersley, 2000). Little research exists on the effectiveness of alternative education, particularly interim alternative educational programs (Bear, 1999; Bear et al., 2001). Research that does exist indicates that alternative educational programs that emphasize punishment and control are associated with poor student attitudes and no reduction in delinquent behavior (Gottfredson, 1997). Research also indicates that an atmosphere characterized by a "community of support" is important to program success (Wehlage, 1991). Features of such a community of support include (Bear et al., 2001) (a) qualified teachers and support staff who volunteer to work with challenging students; (b) flexibility in program management, decision making, and role functions; (c) sufficient funding and resources; (d) sensitivity to individual and cultural differences; (e) clear individual-child and program goals; (f) on-site counseling services; (g) a case management approach to student services; (h) program evaluation; (i) research-supported interventions; and (j) networks of additional supports and services. With respect to interim alternative education settings, it is likely that in addition to the above characteristics, a critical element of success will be the provision of research-supported interventions that are linked to assessment and that are implemented in the setting to which the student returns (Bear et. al., 2001).

SUMMARY

Many persons consider the overarching purpose of education to be the preparation of self-disciplined individuals who become responsible citizens. The linchpin in fulfilling this purpose is school discipline. No longer do we rely on moral exhortations and rote memorization of codes of conduct, however, as the backbone of our discipline programs. Since the turn of the twentieth century, substantial empirical research has accumulated to reveal that effective school discipline programs must be comprehensive, sustained, and composed of three major components: (a) preventive strategies for developing self-discipline and socially responsible behavior, (b) corrective strategies for dealing with misbehavior once it has occurred, and (c) remediation programs for addressing chronic and serious behavior problems.

Research indicates that within each discipline component, multiple factors must be targeted, including how children think, feel, and act; student-teacher relationships; the classroom environment and curriculum; and home and community influences. Of particular relevance are the findings on the characteristics of effective teachers, the importance of fostering social problem-solving skills and social competence in children, and the utility of conducting functional behavioral assessments prior to implementing corrective measures. Schools that address the three major discipline components and multiple factors within each component are successful in creating safe and orderly learning environments as well as in developing self-disciplined and responsible citizens.

ANNOTATED BIBLIOGRAPHY

Brophy, J. E. (1996). *Teaching problem students.* New York: Guilford.

Based on both research and practice, this book describes strategies that teachers have found effective in promoting self-discipline among students. A variety of behaviors are addressed, including hyperactivity, defiance, and rejection. Specific strategies for preventing and responding to these behaviors are presented, along with more general teacher characteristics.

Elias, M. J., Zins, J. E., Weissberg, R. P., Frey, K. S., Greenberg, M. T., Haynes, N. M., Kessler, R., Schwab-Stone, M. E., & Shriver, T. P. (1997). *Promoting social and emotional learning: Guidelines for educators.* Alexandria, VA: Association for Supervision and Curriculum Development.

More than 100,000 copies of this book have been sold. Based on multiple theories, research, and their experiences in the schools, the authors provide educators with practical guidelines and multiple strategies for developing social and emotional competence.

Jones, V. F., & Jones, L. S. (2000). *Comprehensive classroom management: Creating communities of support and solving problems* (6th ed.). Boston: Allyn & Bacon.

Among the many basic texts on classroom management, this is perhaps the best because it offers a comprehensive and balanced perspective on the prevention and correction of common classroom behaviors. Unlike other texts that present multiple models of school discipline with little supporting research, this text highlights strategies of demonstrated effectiveness.

Poland, S. & McCormick, J. S. (1999). *Coping with crisis: A resource for schools, parents, and communities.* Longmont, CO: Sopris West.

This valuable reference provides practical strategies to school psychologists and others for responding to school crises, including school shootings, suicides, fights, and gang-related violence. Step-by-step guidelines and actual case studies are presented.

63 Best Practices in the Systematic Direct Observation of Student Behavior

John M. Hintze
University of Massachusetts at Amherst
Robert J. Volpe and Edward S. Shapiro
Lehigh University

OVERVIEW

Direct observation is one of the most widely used assessment procedures by school psychologists. In a survey of more than 1,000 school psychology practitioners, Wilson and Reschly (1996) found that of the 26 different types of assessment instruments listed across seven different assessment categories (e.g., ability/intelligence, social/emotional, visual/motor), structured observational methods were ranked highest in terms of frequency of use. Overall, practitioners report that they conduct more than 15 behavioral observations of student behavior during the course of a typical month.

Systematic direct observation refers to observation of behavior other than behavior that has been explicitly elicited by a predetermined and standardized set of stimuli (i.e., test behavior (Salvia & Ysseldyke, 2001)). School psychology practitioners commonly use both naturalistic and systematic direct approaches to observing student behavior. Briefly, naturalistic observation approaches refer to those observational procedures where the observer enters specific situations (e.g., a classroom) and observes all that is going on with no predetermined behaviors in mind. Here, the most common way of recording observations is to keep an anecdotal record of the behaviors that seem important to the observer. In summarizing the information, the observer provides a complete description of the many behaviors and the context in which they occurred.

In contrast, systematic direct approaches to behavioral observation are distinguished by five characteristics (Salvia & Ysseldyke, 2001). First, the goal of observation is to measure specific behaviors. Second, the behaviors being observed have been operationally defined a priori in a precise manner. Third, observations are conducted under standardized procedures and are highly objective in nature. Fourth, the times and places for observation are carefully selected and specified. Fifth, scoring and summarizing of data are standardized and do not vary from one observer to another.

Both naturalistic and systematic direct approaches to observing behavior have proven useful in developing theory and practice related to the assessment and intervention of student behavior. This chapter provides an overview of (a) naturalistic observational procedures, (b) systematic direct observational procedures, and (c) observational instruments as they related to the observation of student behavior in the classroom.

BASIC CONSIDERATIONS

Rationale for the Systematic Direct Observation of Behavior

With the reauthorization of the Individuals with Disabilities Education Act (IDEA, 1997), now more than ever it is absolutely incumbent that school psychologists adopt assessment and evaluation practices that allow for gathering relevant functional information on student behavior and performance patterns. Specifically, sections 300.532(b) and (c) under the *Procedures for Evaluation and Determination of Eligibility* of IDEA indicate that a variety of assessment tools and strategies be used to gather relevant *functional* and developmental information about a child and that they be *validated* for the specific purpose for which they are used. Moreover, section 300.532(d) requires the use of tests and other evaluation materials that include those tailored to assess specific areas of educational need and not merely those that are designed to provide a single general intelligence quotient. Similarly, sections 300.533(a)(1)(ii) and (iii) indicate that as part of the initial evaluation for special education, evaluation data include current classroom-based assessments and *observations* conducted by teachers and related services providers. Once deemed eligible for special education, section 300.347(2)(ii) requires the specification of *measurable* annual goals in the development of the individualized education program that meet each of the child's needs as they pertain to the disability classification. The spirit of IDEA is also seen in the *Principles for Professional Ethics* and *Standards for the Provision of School Psychological Services* of the *Professional Conduct Manual* (National Association of School Psychologists, 2000). Here, school psychologists are required to use assessment techniques and instruments that have established validity and reliability and to adopt assessment practices that increase the likelihood of developing effective educational interventions.

The call for the increased use of systematic direct observational procedures and a movement toward more ecologically sensitive functional assessment practices contrast directly with those of a more traditional approach that have long been the standard in school psychological assessment practices. Table 1 provides a comparison between traditional and behavioral assessment across a number of key fundamentals. Central to the difference between the two is how they view the role and causes of behavior and the type of inferences that can be made from observing behavior. From a behavioral perspective, all behavior is a result of the dynamic interplay between an individual and the environment. Thus, observing a person's behavior is useful only to the extent that it can be used to summarize a person under a specific set of circumstances. Behavior is thought to be specific to a situation. For this reason, assessment needs to be ongoing and direct until a certain level of stability or generalizability is observed. This is in contrast to a more traditional approach whereby observed behavior is assumed to be enduring and stable across all situations and intrapsychic or residing within the individual. For this reason, assessment can be global and static; that is, occurring just once or enough to measure the internal construct.

Table 1. Comparison between behavioral and traditional assessment

	Behavioral	*Traditional*
Causes of behavior	Interaction between individual and environment	Enduring underlying states or traits
Role of behavior	Important as a sample of an individual's behavior in a specific situation	Behavior is important only to the extent that it represents the underlying trait.
Consistency of behavior	Behavior thought to be specific to a specific situation	Behavior assumed to be consistent across time and settings.
Use of data	To describe and quantify behavior under specific conditions. To select appropriate interventions. To monitor effectiveness of interventions.	To describe personality Functioning and etiology. To diagnose and classify. To make prognosis or prediction.
Level of inference	Low.	High.
Comparisons made	Both within and between individual.	Between individual.
Timing of assessment	Ongoing. Before, during, and after intervention.	Before and occasionally after intervention.

Note. Adapted from Goldfried and Kent (1972) and Hartmann, Roper, and Bradford (1979).

BEST PRACTICES IN SYSTEMATIC DIRECT OBSERVATION

Methods of Systematic Direct Observation

Naturalistic Observation

Naturalistic observation refers to the recording of behavioral events in their natural settings at the time they occur, using trained or impartial observers, where descriptions of behaviors require little if any inference beyond that which is observed and recorded (Jones, Reid, & Patterson, 1979). Similar to descriptive, narrative, or anecdotal observations, naturalistic observation employs the recording of salient behaviors and discriminative stimuli as they are observed chronologically in time. For example, a school psychologist might observe a student in the classroom and note the sequence of behaviors or activities that are hypothesized to be important or serve a reinforcing function in maintaining patterns of behavior. If a student is observed to refuse the request of a teacher, then this datum would be noted and recorded as a behavioral observation or event.

According to Wilson and Reschly (1996), naturalistic observation is the most frequently used type of direct observation, used nearly twice as often as other more systematic approaches to observation. The reason for this practice most likely lies in its ease in use and minimal training requirements. In practice, naturalistic observation usually takes the form or makes use of one of two recording methods. The easiest form involves simply observing and noting behaviors and events descriptively or anecdotally as they occur in the natural setting. Typically, such behaviors and events would be recorded in a written fashion, listed chronologically as they appeared in real time. Interpretation is limited to a descriptive account of the types of behaviors and events observed and their temporal ordering in time. Because interpretation is limited, such anecdotal and descriptive accounts cannot be used for making high-stakes decisions. In fact, one of the limitations posed by naturalistic observation is the inclination to "over interpret" the data, or make inferences regarding student behavioral patterns from a limited and unstandardized sample of behavior. Likewise, observers are prone to use confirmatory search strategies whereby increased attention is directed toward those behaviors that confirm the observers' original hypotheses. In both situations, bias in the selection and interpretation of the observation is present.

A second and equally popular method of naturalistic observation involves the use of A-B-C (Antecedent-Behavior-Consequence) observation and recording. Similar to anecdotal or descriptive observational techniques, here the practitioner makes careful note of those environmental arrangements, behaviors, or events occurring just before the behavior of concern is observed (i.e., the antecedent) and what behaviors or events are observed as a result of the behavior (i.e., the consequence). By using the example of refusing a teacher request above, the antecedent would most likely be some type of teacher request or directive, the behavior would be the act of refusing, and the consequence would most likely be a brief description of how the teacher responded to the student refusal. Figure 1 presents an example of the type of recording schedule that is typically used during A-B-C observations. This type of recording schedule can be easily constructed by dividing a sheet of paper into three columns, each of which corresponds to one of the three conditions (i.e., antecedents, behaviors, and consequences). Once constructed, the observer provides a brief narrative of each condition as they are observed in the natural setting. Although listed as A-B-C, the behavior column is generally completed first and then followed by the antecedents and consequences. The reasoning behind this rests on the understanding that without the presence of some salient recordable behavior, there is little use in recording antecedents and consequences. While numerous behaviors will obviously occur, only those of clinical importance are noted. Given this, it is often helpful to specify beforehand those behaviors that will be recorded during the observation period.

Naturalistic observation techniques have become increasingly popular owing in part to their utility as part of an overall functional assessment strategy. Here, descriptive or anecdotal and A-B-C analyses are used as a preliminary step in data collection and serve the purpose of developing testable hypotheses regarding the motivation and maintenance of student behavior. For example, O'Neill et al. (1997) use naturalistic observation strategies as the first step in an overall functional assessment procedure that allows the clinician to operationally define target behaviors and formulate preliminary hypotheses regarding the function of behavior. Once salient behaviors and environmental events are observed naturalistically,

Figure 1. Example of naturalistic observation using A-B-C observation and recording

A-B-C Observation and Recording Sheet

Antecedent	Behavior	Consequence
Teacher asks students to take out paper and pencil.	Target student does not take out paper and pencil. Plays with toy car on desk instead.	Teacher reprimands target student.
Teacher takes paper and pencil out of target student's desk.	Target student pushes paper and pencil off desk and onto floor. Target student puts head on desk with arms folded around head.	Teacher removes request. Teacher picks up paper and pencil and places on desk. Tells target student he can begin work when he calms down.
Teacher continues lesson with rest of class.	Target student begins to play with car on desk again.	Teacher stops lesson and takes car away from target student.
Teacher directs student to put name on top of paper.	Target student kicks desk away. Sits in chair with arms folded across chest.	Teacher ignores target student.

they are observed systematically by using time-sampling procedures.

The advantages of using naturalistic observation procedures to identify target behaviors in this manner are that (a) their importance or social validity of behaviors can be assessed by noting the frequency of their occurrence in the natural setting, (b) their relationship to important environmental antecedents and consequences can be examined systematically, (c) data can be used to develop testable hypotheses regarding the function of behavior, and (d) the data gathered serve an important step in allowing the clinician to make decisions regarding the function of behavior rather than focusing on topographical and descriptive accounts of what is observed. As was previously noted, one of the restrictions of natural descriptive accounts of behavior is their limited utility in decision making. Because the data gathered are purely descriptive in nature, decisions are restricted to summary statements of what was observed and little else. For the most part, such data prove limited in a more problem-solving assessment orientation. Nonetheless, naturalistic descriptive accounts can be extremely useful when used as a preliminary step in a problem-solving functional assessment paradigm. Here the data gathered form the basis for developing initial hypotheses that can be subsequently observed in a more systematic fashion. The next two sections describe such systematic observational methods and the way in which practitioners can use such methods to quantify behavior from an ecological perspective.

OBSERVATIONAL PROCEDURES

Observational procedures refer to a set of techniques that school psychologists can use to quantify behavior along one or multiple dimensions (Kratochwill, Alper, & Cancelli, 1980). For example, a school psychologist might be interested in assessing the frequency in which a referred student is out of his seat. After operationally defining the behavior of interest, the target child would be directly observed for a specified length of time with the number of times he got out of his seat noted. Additionally, the length of time spent out of his seat for each occurrence might be noted. If out-of-seat behavior does not appear to be the main issue of concern, then another behavior can be specified and observed in a similar manner. Likewise, multiple behaviors can be identified and observed concurrently. Although the example is oversimplified, here the advantages of using observational procedures are that they are flexible and can be tailored to suit the specific needs of the assessment situation.

Measuring and Recording Behavior Systematically. There are various types of data that can be collected during systematic direct observation. A workable definition of a target behavior is one that provides an accurate description of the behavior that clearly defines the parameters of its existence and nonexistence (Heward, 1987). As such, constructs and reifications do not lend themselves well to direct observation. For example, raising one's hand to be called on is an observable and measurable behavior. Behaving "off the wall" is not something that can be directly observed. In developing explicit behavioral definitions Hawkins and Dobes (1977) offer the following suggestions:

1. The definition should be objective, referring only to observable characteristics of the behavior and environment.

2. A workable behavioral definition is readable and unambiguous such that an experienced observer could read it and readily paraphrase it accurately.

3. The definition should be complete, delineating the boundaries of what is to be included as an instance of the behavior and what is to be considered a noninstance of the behavior.

As such, operational definitions must be objective, ensuring that specific instances of the defined target behavior can be readily observed and recorded. In addition, an operational definition is a technological definition that enables others to use and replicate it (Baer, Wolf, & Risely, 1968). A complete operational definition identifies what is not the target behavior and aids observers in discriminating the target behavior from similar responses.

Once behavior is defined, the calibration of the operational definition is determined by the nature of the data; that is, the frequency of its occurrence and the particular interests of the observer (Hintze & Shapiro, 1995). In addition, practical considerations such as the availability of observers, the amount of time the student is accessible, or any combination of these factors, all dictate the type of data collected. Because each of these data may yield different results, the method of data collection must be clearly understood.

Frequency or Event Recording: The type of data known as frequency or event recording involves counting the number of occurrences of behavior observed during a specified time period. When the time periods in which the behavior is counted vary, frequencies are converted to rates of behavior per unit of time. For example, an observer may report that a target child raised a hand at an average rate of one time per minute during three separate observations conducted over the course of three days, even though the actual duration of each observation period varied. By using rate of behavior allows the practitioner to compare the occurrence of behavior across observational periods (Shapiro, 1987).

Frequency or event recording is most useful when observing behaviors that have a discrete beginning and ending. Throwing paper airplanes, hitting, and the raising of a hand are all examples of such behaviors. Behaviors that are continuous or persist for longer durations sometimes prove difficult to observe by using event recording. For example, pencil tapping, talking, or on-task behavior would be difficult to observe by using such an observational system. As with all recording schedules, a very clear operational definition of the target behavior helps ensure that accurate frequency data are being collected. In instances such as pencil tapping and talking, episodes of the behavior may be defined by using a time dimension as well as a topographical description of the behavior. For example, pencil tapping may be defined as the continuous tapping of the pencil against a physical surface that produces audible noise for at least five consecutive seconds. In this way, the frequency count for pencil tapping is easily recorded rather than the actual number of times the pencil is tapped against a physical surface.

A second consideration when using event recording has to do with the actual length of time each episode of the behavior occurs for. Generally speaking, each episode of the behavior should take approximately the same amount of time for each instance of the behavior (Barton & Ascione, 1984). For example, if an observer is observing occurrences of "noncompliance," the length of time might vary widely from a simple refusal to follow a direction to a knock-down drag-out tantrum that lasts 20 minutes. Because each episode would be coded as the occurrence of one act of noncompliance, each would be weighted equally in terms of the way in which it was quantified. Obviously, the variability in the duration of each episode is lost. For this reason, when the length of time a behavior occurs is important, event recording might not be the most appropriate recording schedule. It may, however, be combined with other recording options (e.g., duration) to capture both frequency and time dimensions of a particular behavior.

Another instance in which frequency or event recording is particularly useful is when behavior occurs at a relatively low rate. Such behaviors often occur infrequently but are of interest because of their intensity or seriousness. For example, running out of the classroom may occur once or twice a day, but may represent significant difficulties for the student. The advantage here is that with low frequency behaviors, observational periods can be continuous and designed in a fashion to be relatively unobtrusive and at low time and cost to the observer. The disadvantage, however, is that if any instance of the behavior is not observed and recorded, the reliability of the observed data is sacrificed.

As can be seen, the methods for frequency or event recording are quite varied. Commonly, the frequency in which behavior occurs is recorded in a written format (e.g., tallies on a piece of paper) with the beginning and ending time of the observational session noted. In addition to simple paper-and-pencil recording, hand-held mechanical recorders such as those used to keep track of attendance at a social function, golf wrist counters, or a wrist abacus can be used. In the end, any device capable of keeping a cumulative frequency count can be used to perform event recording. Figure 2 presents an example of a paper-and-pencil frequency recording schedule.

Duration Recording: Another type of behavioral response that can be recorded is the duration of the behavior. Duration measures may be very helpful with certain types of school-related behaviors. Studying, temper tantrums, social isolation, and aggressive outbursts are good examples of behaviors in which duration is generally important. Duration is also appropriate in cases where changing the duration of the behavior is an important target for intervention. As in the case of event recording, behaviors that have discrete beginnings and endings may be assessed in the length of time the behavior lasts.

The duration of a behavior is usually standardized in two ways (Salvia & Ysseldyke, 2001). First, the average duration of each occurrence may be computed. For example, Gary got up and out of his seat five times during a 20-minute observation. The duration of each episode was 2, 3, 4, 5, and 6 minutes, respectively. In this case the average duration was 4 minutes (i.e., [2 + 3 + 4 + 5 + 6]/5). Second, the total duration may be computed. In this same example, Gary was out of his seat a total of 20 minutes.

The most precise nonautomated instrument for collecting duration data is a stopwatch. The procedure for recording total duration with a stopwatch is to start

Figure 2. Example of frequency recording. Target behaviors include getting out of seat (OS), calling out (CAL), and teacher redirections (TR)

Frequency Observation and Recording Sheet

Date: May 13, 2000

Observer: A. VanDelay

Time	OS	CAL	TR
9:00 a.m.–10:00 a.m.	X X X	XXXXX	XXXXXXX
10:00 a.m.–11:00 a.m.	X	XXX	XXXX
11:00 a.m.–12.00 p.m.	XX	X	XXXXXX

the stopwatch as the behavior begins and stop the timing at the end of the episode. Without resetting the stopwatch, the observer starts the stopwatch again at the beginning of the second occurrence of the behavior and stops timing at the end of the second episode. The observer continues to accumulate the durations of time in this fashion until the end of the observation period and then transfers the total duration of time showing on the stopwatch to a record sheet. Figure 3 presents an example of duration recording for thumb sucking.

When observation sessions are consistent in length (e.g., 20 minutes), total duration can be compared across sessions. However, when observation sessions vary in length, a percent ratio of total duration to observation length must be computed before comparisons across observational sessions can be made. For example, if the total duration of Gary's out-of-seat was 10 minutes in each of three observational sessions but the observational sessions varied from 20-, to 30-, and 40-minute time frames, then the total duration percent that he was out of his seat would be noted as 50, 33, and 25%, respectively.

The procedure for recording duration per occurrence with a stopwatch is to start the stopwatch as the behavior begins and stop the timing at the end of the episode. The observer transfers the duration of time showing on the stopwatch to a data sheet and resets the watch. The stopwatch is started again at the beginning of the second occurrence of the behavior and is stopped at the end. The duration of time for each episode is then summed and divided by the number of occurrences yielding an average duration per episode.

Latency Recording: Latency recording is the measurement of elapsed time between the onset of a stimulus or signal (e.g., a verbal directive) and the initiation of a specified behavior (Cooper, 1987). Latency recording should be used when the major concern is the length of time between an opportunity to elicit a behavior (e.g., after the presentation of the verbal directive) and the actual time it takes to begin performing the behavior. In this case, the response latency would be the length of time between the end of the teacher's directive and initiation of the student's compliance with the directive. As with event and duration recording, when latency is assessed, both the signal and the behavior of interest must have discrete beginnings. The procedure for latency recording is similar to that for duration recording. The observer uses a stopwatch and begins timing immediately after the signal or stimulus is delivered and stops timing at the instant the target behavior is initiated. For each

Figure 3. Example of duration recording for thumb sucking

Duration Observation and Recording Sheet

Student: Alex

Behavior: Thumb Sucking
Date: August 5, 2000

Time start: 10:10
Time stop: 10:30

Thumb sucking (separate incidents)	Elapsed time per episode (in minutes and seconds)
1	1' 17"
2	6' 42"
3	2' 11"
4	7' 26"
5	52"
	Total: 18' 28"

Average duration per episode, 3' 42"

episode, the summary datum is the time lapse between the signal and the behavior. The actual time that it takes to complete the target behavior *does not* figure into latency recording. This is because behaviors can vary widely in the time it takes to complete them. For example, the directive of "pick up your pencil and put your name on the top of the paper" and "pick up your pencil and complete the *New York Times* Sunday crossword puzzle" would each be expected to have similar latencies. Obviously, the duration of these two behaviors would vary significantly. If completion times of these two behaviors were of primary interest, then duration would be an appropriate recording schedule. Moreover, like duration, both average and total latency can be used to summarize observed behaviors.

Time-Sampling Interval Recording: Whereas frequency, duration, and latency recording are able to accurately capture the dimensions of behavior each represents, oftentimes it is difficult to use any one of the recording schedules because of practical or measurement concerns. Issues dealing with availability of observers, lack of time, or operational issues (e.g., complications in determining exact beginning and ending of behavior) all contribute to the difficulty in observing behavior continuously. The essential characteristics of time sampling interval recording involve selecting a time period for observation, dividing the observational period into a number of equal intervals, and recording whether or not a specified target behavior has occurred during each interval (Merrell, 1999). For example, a 30-minute observation period might be broken down into 120 15-second intervals. Within each interval, the presence or absence of one or multiple behaviors might be assessed. Presence or absence of the behavior will be determined by one of three, or any combination, of three recording schedules discussed below (i.e., whole, partial, or momentary time sampling recording).

Also, unlike event, duration, and latency recording that provide exact frequency or time dimensions of observed behavior, time sampling interval recording provides only approximates for the behavior as it occurs. That being so, for situations where the exact number of occurrences or time spent engaged in the behavior, or latency of the behavior is of concern, time sampling interval recording might not be the best option. Nonetheless, time sampling interval recording provides an excellent alternative when conditions warrant observing a number of behaviors simultaneously, or for behaviors that occur at a moderate to high rate or steady state.

Whole-Interval Recording: In whole interval recording, the target behavior is scored as having occurred only when it is present throughout the entire interval (intervals are scored usually with a plus sign or other mark to indicate the presence of the behavior, and empty intervals generally denote the absence of the behavior). Since the behavior must be present for the entire interval, whole-interval recording lends itself quite well to behaviors that are continuous or intervals that are of a short duration (Shapiro & Skinner, 1990). One of the drawbacks of whole-interval recording, however, is that has a tendency to underestimate the presence of the behavior in real time. Consider for example, a whole-interval recording schedule where each interval is 15 seconds long. If, for example, off-task behavior were our target behavior and it was observed for 13 of the 15 seconds during the interval, then the interval would not be scored for the presence of off-task behavior since it did not occur for the entire 15-second interval. In essence, it would appear as if the target student was on-task for the entire 15 seconds. Because of this, whole-interval recording is well suited for behaviors targeted for increase through intervention efforts (Sulzer-Azaroff & Mayer, 1991).

Partial-Interval Recording: In contrast to whole-interval recording, with partial-interval recording an occurrence of the behavior is scored if it occurs during any part of the interval. Thus, if a behavior begins before the interval begins and ends within the interval, then an occurrence is scored. Similarly, if the behavior starts after the beginning of the interval, then an occurrence is scored. Finally, if multiple occurrences of the behavior are observed within the same interval, then the interval is simply scored as if the behavior occurred once. Again, in comparison to whole-interval recording, partial-interval recording is a good choice for behaviors that occur at a relatively low rate or behaviors of somewhat inconsistent duration. Also, partial-interval recording tends to overestimate the actual occurrence of the behavior. By using the example above, if the target student were observed to be off-task for only 2 seconds of the 15-second interval, then the interval would be scored for the presence of the behavior as if it occurred for the entire 15-second interval. Because of this, partial-interval recording is well suited for behaviors targeted for decrease through intervention efforts (Sulzer-Azaroff & Mayer, 1991).

Momentary Time-Sampling: Finally, with momentary time-sampling, a behavior is scored as present or absent only during the moment that a timed interval begins. With this technique, the observer notes either the presence or absence of the behavior at a brief instant during the interval. By using the above example, the target student would be considered off-task if at the moment of observation (e.g., very beginning of a 15-second interval) he was observed to be off-task, irrespective of any behavior observed during the rest of the interval. Salvia and Hughes (1990) have summarized a number of studies investigating the accuracy of these time-sampling procedures. As was previously noted, both whole-interval and partial-interval sampling procedures provide inaccurate estimates of the behavior in real time. Momentary time-sampling, although based on the smallest sample of behavior, provides the least biased estimate of behavior as it actually occurs (Suen & Ary, 1989).

OBSERVATIONAL INSTRUMENTS

In contrast to observational procedures, observational instruments have been developed to assess a specific range of behaviors. For example, a school psychologist might choose to use an observational instrument designed specifically to quantify the percentage of time a student is academically engaged or off-task or the frequency with which a teacher provides directives, provides opportunities to respond, or positively reinforces student efforts. Unlike more generic observational procedures, however, the flexibility of observational instruments is typically limited. With standardized administration and scoring procedures, practitioners cannot alter the operational definitions to suit their individual needs. However, because they have been developed with a specific purpose in mind, observational instruments tend to provide a more detailed account of a student's behavioral pattern across a variety of behaviors of common interest to the observer. What is lost in flexibility is gained in breadth of behaviors observed. While school psychologists could certainly develop their own observational instruments individually tailored to particular behavioral constructs, the time spent in development may be cost and labor prohibitive.

Nonetheless, the use of observational instruments continues to gain in popularity. The increased interest in such techniques is due in part to the optimization of laptop computers and hand-held data recording devices. What follows are two examples of published systematic observation codes. The Behavior Observation of Students in Schools (BOSS) (Shapiro, 1996) can be a useful part of an academic assessment in classroom settings. It may also be used in assessments of disruptive behavior, if aggressive behavior is not of principal concern. The Attention Deficit Hyperactivity Disorder School Observation Code (ADHDSOC) (Gadow, Sprafkin, & Nolan, 1996) was specifically designed to assess disruptive child behavior across a number of school settings and includes various measures of aggressive child behavior. These specific codes were selected for review owing to their ease of use, and their differential purposes.

Behavior Observation of Students in Schools. The BOSS is a useful observation code for assessing child academic behavior in the classroom environment. It is a relatively easy code to learn and use. In simple terms, the BOSS assesses levels of "on-task" and "off-task" behavior. The amount of time children are engaged in academic tasks appears to be an important instructional variable (see Gettinger, 1986, for a review). Although several existing observation codes include behaviors that represent academic engagement, the BOSS is unique in that it divides engagement into two categories: (a) active engagement (e.g., writing, raising hand, answering a question) and (b) passive engagement (e.g., looking at a worksheet, listening to teacher directions). Furthermore, off-task behaviors are assorted into three categories: (a) off-task motor (e.g., out-of-seat, fidgeting, playing with pencil), (b) off-task verbal (e.g., calling out, talking to a peer when prohibited), and (c) off-task passive (e.g., looking around, looking out the window). Finally, the BOSS also includes a measure of teacher directed instruction (TDI), which provides an estimate of the amount of time the teacher is engaged in direct instruction. For example, the TDI category would be scored as present if the teacher were lecturing to the class and absent if the teacher were sitting at the desk correcting papers.

The BOSS is administered in 15-second intervals for a period of at least 15 minutes. The on-task behaviors (i.e., active and passive engagement) are scored at the beginning of each interval by using momentary time-sampling. For the remainder of each interval, the off-task behaviors (i.e., motor, verbal, and passive) are noted by using partial interval scoring. In addition, during every fifth interval, rather than observing the target student, the behavior of a randomly selected peer is observed and noted. In doing so, comparisons can be made between the target student and a peer composite that represents "typical" behavior during the observational period. Once the observation is completed, scoring summaries are computed for on- and off-task behaviors of both the target student and the peer composite, as well as an overall estimate of how much time the teacher was engaged in direct instruction.

Attention Deficit Hyperactivity Disorder School Observation Code. According to its authors, the ADHDSOC was developed as both a screening measure and as a tool for evaluating the effects of interventions for children diagnosed with attention-deficit/hyperactivity and related disorders (e.g., oppositional defiant disorder). The ADHDSOC can be used across a number of school settings (e.g., classroom, lunchroom, playground). For example, the following seven behavior categories are scored in classroom situations: (a) interference (e.g., target student calls out when it is inappropriate to do so), (b) motor movement (e.g., target student gets out of seat without permission, (c) noncompliance (e.g., target student ignores verbal direction from teacher or aide), (d) verbal aggression (e.g., target student curses), (e) symbolic aggression (e.g., target student takes another student's pencil), (f) object aggression (e.g., target student kicks chair or desk), and (g) off-task (e.g., target student stops working on assignment and stares out the window). Though the various aggression scores (i.e., verbal, symbolic, object) may be coded individually, the authors suggest collapsing them into a single category termed "nonphysical aggression." For observations conducted in the lunchroom or on the playground the following categories are coded: (a) appropriate social behavior (e.g., target student is observed talking to another child appropriately), (b) noncompliance, (c) nonphysical aggression (this includes both object and symbolic aggression), (d) verbal aggression, and (e) physical aggression (e.g., target student trips another child). Across all settings, target behaviors are scored on a partial interval every 15 seconds.

For diagnostic purposes, the authors recommend selecting three or four average peers to observe for comparison. Selected peers and the target student are then observed in alternating 1-minute intervals. The observer rotates through each peer until all have been observed, and then returns to the initial peer. Specific guidelines for collecting observation data as well as statistical guidelines for comparing the scores of the target student to the peer composite are provided. In addition, guidelines for incorporating the ADHD-SOC into treatment evaluation procedures are also presented. Validation of the ADHDSOC is presented in several studies of school-based medication evaluation studies (see Gadow, 1993; Gadow, Nolan, Poalicelli, & Sprafkin, 1991).

Both the BOSS and the ADHDSOC are relatively simple school-based observation codes to learn and use. They offer the opportunity to assess both within-student features of behavior (e.g., across various settings that vary with respect to task demands), and between-student features of behavior (e.g., target student as compared to peer composite). These are only two of the many coding systems available to school psychologists. Other available instruments are listed in Table 2.

General Issues in Systematic Direct Observation

CONSIDERATIONS IN SELECTION OF TARGET BEHAVIORS

Considering the Social Significance of the Behavior. In daily practice, it is not uncommon for teachers and other school personnel to describe a litany of target behaviors that present as possible candidates for change. As most school psychologists are all too well aware, to target each for observation and intervention is likely to prove time and cost inefficient in the long run. As such, assessment information gathered before systematically observing behavior (e.g., interviews) is absolutely crucial to designing a sound observation strategy. In doing so, the school psychologist must determine which elements of a student's behavioral repertoire might serve as socially significant and ecologically valid target behaviors (Hintze & Shapiro, 1995).

Table 2. Other examples of school-based observation protocols

Code	*Published*	*Age group*	*Setting*	*Recording schedule*	*Length of intervals, seconds*

[a] Sinclair, Del'Homme, and Gonzalez (1993).

Procedures that affect behavior of one or more persons in ways that increase the probability or magnitude of benefits for any one or all of the persons involved are considered to be socially valid targets for behavior change (Hawkins, 1986). Teaching children to read, pay attention, or make friends with peers are likely to be socially valid, because these efforts generally increase benefits and decrease costs for both the targeted individual and the rest of society (Hawkins, 1991). As such, a goal, outcome, or procedure is valid only to the extent that choosing it as a target for change improves the benefit-to-cost ratio for the individual, for others, or both. A consumer's or professional's opinion about a targeted behavior for change is only valid to the extent that it is consistent with such improved benefit-to-cost ratio (Hawkins, 1991).

Although conceptually the notion of social validity makes sense, in practice it may be difficult to operationalize. At least one objective validation strategy is to use normative data from same age peers as the target student to identify which behaviors are likely to be adaptive, and the extent to which such behaviors are expected to be mastered. For example, observing the rates of academic engaged time of peers of the target child can help establish whether or not a discrepancy is present, in addition to the magnitude of the discrepancy and goals for change (Hawkins, 1991). Similarly, observing those behaviors considered to be associated with targeted behaviors (e.g., escape or avoidance) from a normative reference group may assist in determining which behaviors are of critical importance for success (Hawkins, 1991). Finally, the best validation of which behavior is most adaptive is to test experimentally the outcomes produced by different behaviors and different levels of their performance (Hintze & Eckert, 2000). By definition, those strategies that yield the greatest benefit at the least cost are the most adaptive (Hawkins, 1986).

Prioritizing Possible Target Behaviors. In many assessment situations, decisions must be made regarding the relative priority of possible target behaviors (Hintze & Shapiro, 1995). In a review of the research, Nelson and Hayes (1979) offer four suggestions that can help guide the practitioner faced with a multitude of potential target behaviors:

1. Alter the behavior that is most irritating to the person who has identified the problem (Tharp & Wetzel, 1969).

2. Alter a behavior that may be relatively easy to change (O'Leary, 1972).

3. Alter behaviors that will produce beneficial response generalization (Stokes & Baer, 1977).

4. When behaviors exist as part of a longer response chain, alter the behaviors at the beginning of the chain (Angle, Hay, Hay, & Ellinwood, 1977).

In addition, Hawkins (1986) suggests that:

1. Targeted behaviors should be those that represent "keystone" or pivotal behaviors within a behavioral response hierarchy.

2. Behaviors that have a "general utility" should be considered prior to those with highly specific functions.

3. The construction or acquisition of behavioral response repertoires should take precedence over the pure elimination of specific behaviors.

4. Behaviors that gain a student access to reinforcement in the natural environment should be given high priority.

5. Student choice should be considered when selecting possible target behaviors.

Antecedents and Consequences of Behavior. Both naturalistic observation and systematic direct observation strategies allow the observer to examine interdependencies among functional antecedents, behaviors, and consequences (Alessi, 1988). Careful examination of such functional response chains allow practitioners to develop hypotheses such as:

1. Are there avoidance, escape, or termination behaviors evident, contingent upon requests or demands made by the teacher?

2. Does the magnitude of the behavior change as a function of varying task demands?

3. Does the target behavior lead to accessing social attention or preferred tangibles or activities?

4. Are there particular setting or temporal characteristics associated with the target behavior?

Once developed, such hypotheses can be tested experimentally in a more controlled experimental analysis of the behavior (Iwata, Dorsey, Slifer, Bauman, & Richman, 1982). By using a brief functional analysis (Wacker et al., 1990), hypothesized behavioral functions can be assessed using predetermined analogue assessment strategies. Most assessments include alone, escape, and attention conditions. During the first phase of the analysis, reinforcement (e.g., social attention, withdrawal of a demand) is provided contingent on the occurrence of the target behavior. During the second phase of the brief functional analysis each condition is replicated; however, the reinforcement contingency (i.e., escape, attention) is provided for appropriate behavior rather than inappropriate behavior. By using such a methodology allows the practitioner to validate specific A-B-C chains and target specific environmental contingencies for ongoing assessment and intervention.

SUMMARY

Significant effort has been made over the past decade to shift the role of the school psychologist from one of problem identifier to one of problem solver (Deno, 1995). With a focus on hypothesis testing and scientific accountability, the school psychologist as problem solver seeks to use assessment instruments that provide clear links between assessment and intervention. Systematic direct observation provides one of the most useful strategies for accomplishing this goal. With a focus on socially significant and meaningful behavior change, systematic direct observation changes the approach of the observer from passive to active and reflects technological advances in both the study of human behavior and how behavior is recorded and summarized. Moreover, systematic direct observation procedures are in line with the reauthorization of IDEA and current standards for test use among school psychologists.

As with any new skill, it takes time to become fluent in the use of systematic observations. School psychologists should not be fooled by its apparent simplicity and should expect to devote as much time in training to use such procedures as they typically would in learning any standardized assessment instrument. With continued use, however, school psychologists will find systematic direct observation to be a crucial component of just about any of the services they offer.

Best Practices in Functional Behavioral Assessment for Designing Individualized Student Programs

Timothy P. Knoster
Bloomsburg University of Pennsylvania
Barry McCurdy
Devereux Institute of Clinical Training and Research

OVERVIEW

It is only 8:10 in the morning, and, once again, John is sent to the principal's office for fighting with his classmates. He passes Carmen, who has recently received her fourth disciplinary referral this week (and it is only Wednesday) for disruptive and disrespectful behavior during classroom instruction. Down the hall from Carmen's classroom, Drew's Individual Education Plan (IEP) team is scheduling yet another meeting after school to modify Drew's behavior intervention plan in response to his increasing self-injury (i.e., face slapping and scratching). Last night, the parents of four kindergarten students requested a meeting with the principal concerning a young boy's use of profanity and his intimidation of their sons or daughters.

Everyday, schools in America are faced with complex challenges related to educating increasingly diverse student populations, especially students with chronic problem behavior. Although these students typically represent a small portion of school enrollment (i.e., 1–5%), they often account for more than 50% of the behavioral incidents handled by office personnel and consume significant amounts of time (Sugai et al., 2000; Sugai, Sprague, Horner, & Walker, 2000; Taylor-Greene et al., 1997). It is also likely that many of these same students will require individualized comprehensive behavioral supports that involve family, school, and community participation (Eber, 1996; Eber & Nelson, 1997). Also, only some of these students are likely to be eligible for special education services and programs.

School psychologists are often asked by school personnel or by parents for guidance in treating these students and are in a prime position to facilitate the design and delivery of comprehensive behavior intervention plans based on functional behavioral assessment (FBA).

The specific issue of how FBA should be integrated into the special education decision-making process is a matter that must be addressed by IEP teams (Tilly et al., 1998). FBA is required in the Individuals with Disabilities Education Act (IDEA) only when students with disabilities become the subject of school discipline proceedings. Section 615(k)(1)(B)(i) of the statute states:

> Either before or not later than 10 days after taking a disciplinary action described in subparagraph (A). . . if the local educational agency did not conduct a functional behavioral assessment and implement a behavioral intervention plan for such child before the behavior that resulted in the suspension described in subparagraph (A), the agency shall convene an IEP meting to develop an assessment plan to address that behavior.

While literally accurate, such a narrow interpretation has a series of shortcomings given a broader reading of the statute. Contrarily, a rationale for a broader interpretation can be built on IDEA statutory language for implementing FBA throughout the special education decision-making process. This position stems from a series of interactions between related sections of the statute.

In particular, §614(b)(2)(A) states that in conducting full and individual evaluations for any student suspected of having a disability, "the local education agency shall use a variety of assessment tools to gather relevant functional and developmental information . . . ." While the term "functional" in this passage modifies the word "information," it is not clear how functional information could be collected as part of a full and individual evaluation outside the context of an assessment. In addition, section 614(b)(3)(D), states that "[e]ach local education agency shall ensure . . . assessment tools and strategies that provide relevant information that directly assist persons in determining the educational needs of the child are provided." Thus, regardless of what information is collected to document the presence of a disability, teams must collect information in all relevant domains where the student demonstrates educational need. So, when the requirements of §614(b)(2)(A) and §614(b)(3)(D) are read together, the following implications seem clear: If a student with a disability experiences difficulties with mobility, reading, or other related skill areas that impede learning regardless of specific disability, then a developmental and functional mobility (reading, etc.) assessment is warranted. Given this interpretation, it may then be further inferred that if behavioral issues are of concern, then a developmental and functional behavioral assessment would contribute important information as part of the full and individual evaluation.

In further support of this broader interpretation, the IEP section of the statute states a series of clear expectations that positive behavioral programming be provided to IDEA-eligible students who need it. Section 614(d)(3)(B)(i) of the statutes states that "in the case of a child whose behavior impedes his or her learning or that of others, consider, where appropriate, strategies, including positive behavioral interventions, strategies and supports, to address the behavior." The design of positive behavioral interventions, strategies, and supports are precisely the purpose for which FBA was developed (O'Neill et al., 1997). FBA procedures should be used as part of positive behavioral intervention development for students and, in particular, for students with disabilities whose behavior impedes their learning or the learning of others.

The final reference in the statute that supports the use of FBA in situations beyond discipline comes from the discipline section itself. Section 615(k)(1)(B)(i) states, "if the local educational agency did not conduct a functional behavioral assessment and implement a behavioral intervention plan . . . ." Thus, the law acknowledges the use of FBA beyond the context of the discipline section for students with disabilities who exhibit problem behavior.

In light of this broad interpretation, school psychologists can and should provide proactive leadership by advocating for, and implementing, the FBA process for all students evidencing increasingly significant problem behavior. Further, school psychologists are in a unique position to provide policy guidance in their respective educational agencies concerning promising and best practices (i.e., functional assessment). School psychologists, in responding to this opportunity, should have a thorough understanding of the inter-relationship between research, policy, and practice as it pertains to functional behavioral assessment. Specifically, current knowledge of the literature coupled with a practical understanding of school policy, as well as an understanding of factors that inhibit or enable the implementation of best practice, is required of school psychologists.

BASIC CONSIDERATIONS

Functional behavioral assessment is a problem-solving framework that leads to intervention. The decision-making process employed by an educational team does not change across settings or situations. However, the level of resources and precision needed to effectively intervene will vary based on need and the circumstances confronted by the educational team (i.e., intensity, severity, and durability of the given student's problem behavior across settings).

There are five general considerations that school psychologists should take into account when conducting FBAs in schools. These considerations are presented in Table 1.

Table 1. Basic considerations

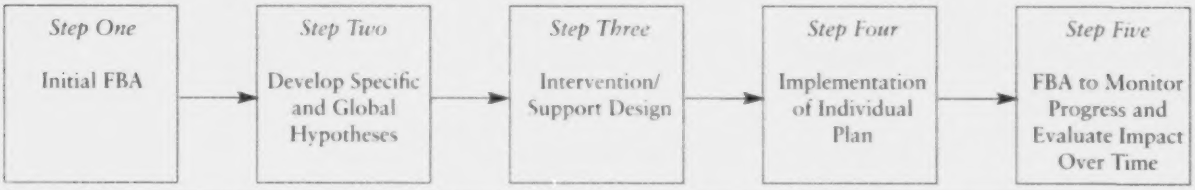
Consideration	*Implications for Practice*
FBA: Intervention link	The behavior of the focus student and others in typical routines and settings (contexts) should serve as the focal point of FBA. Information gathered through the FBA should be summarized in the form of specific and global hypotheses to drive intervention design.
FBA procedures: Continuum	No one interview or direct observational protocol will serve all situations. It is important to create the appropriate match between (a) the resource and precision of assessment and intervention procedures selected and (b) the intensity, severity, and/or durability of problem behavior (Tilly et al. 1998).
FBA: Special education decision making process	FBA (in varying degrees and form) should be conducted as a means to design effective teaching strategies for students who present behavior that impedes their learning or that of others. Therefore, FBA may be conducted at varying points in time throughout the special education decision-making process.
FBA: Critical components	Selected FBA procedures should reflect a problem solving process that will help an educational team answer four questions: • What is the problem? (Initial FBA) • Why does the problem exist? (Initial FBA) • What should be done to address the problem? (Initial FBA) • Did the intervention work and what's next? (FBA in progress monitoring)
FBA: Professional development	School psychologists must be aware of current best practices in conducting FBA and have an understanding of policy and practice implications (e.g., process skills). In particular, school psychologists are in a prime position to guide professional development for teachers and other relevant parties on FBA procedures.

FBA and the Link to Intervention

For an FBA to be functional, it must lead to the development of a plan for intervention and support that has a high likelihood of success. An important role for school psychologists is to effectively communicate this expectation among colleagues in schools.

The process of conducting an FBA involves gathering broad and specific types of information. As a standard practice this includes the use of informant methods with people who (a) know the child well, (b) work with the child on a regular basis, and/or (c) will be directly affected by the results of intervention. It is important to involve these same individuals from the onset of the initial FBA through design, implementation, progress monitoring, and program modification phases of the intervention process. Meaningful involvement by relevant parties will not only increase the likelihood that accurate and useful information is obtained, but also facilitate design and implementation of intervention and support that fit naturally occurring routines and settings (e.g., daily classroom routines). Relevant parties should participate (to varying degrees) in each of the five steps in the process, as highlighted in Table 2.

Table 2. Five step planning process for effective behavior support



Step One
Initial FBA
Step Two
Develop Specific and Global Hypotheses
Step Three
Intervention/ Support Design
Step Four
Implementation of Individual Plan
Step Five
FBA to Monitor Progress and Evaluate Impact Over Time

FBA and the Procedural Continuum

The process of conducting FBAs can best be understood as a continuum of integrated assessment procedures that may involve a broad array of data collection tools and procedures. Determining the appropriate level of resource and precision of intervention (including FBA) should be made on a case-by-case basis in relation to the degree of need experienced by the educational team, as depicted in Figure 1.

To illustrate, mild problem behaviors (e.g., occasional and infrequent aggressive actions such as pushing other children on the playground) can be initially assessed through informant methods by simply asking teachers about the setting and circumstances under which the student is aggressive towards others and the consequences that occur after the student has been aggressive. Alternately, an educational team confronted with the need to conduct a more rigorous FBA for a student who engages in high levels of a serious problem behavior that prior interventions and supports have failed to ameliorate (e.g., chronic aggression toward other students in the form of hitting, scratching, and biting), will likely need to employ informant methods (e.g., in-depth interviews) in conjunction with more resource-intensive behavioral observations across settings and time. School psychologists, acknowledging this continuum, are in a unique position to guide team decision making by creating a conducive match between intensity/severity/durability of the student's problem behavior and mitigating circumstances and resources and precision of the assessment procedures employed to design intervention and support.

Figure 1. Conceptual relationship between degree of behavioral problem and resource and precision of intervention

Resource and Precision of Intervention

Adapted from Tilly et al., 1998.

In a practical sense, it is important to understand that student-centered teams will likely enter into the process of conducting initial FBAs at varying points in the educational decision-making process ("points of entry"). Two practical illustrations include (a) a third-grade student's persistent tantrums that have prompted a full and individual evaluation for consideration of eligibility and need for special education and (b) an eighth-grade student with an IEP for whom, as a result of Manifestation Determination, the IEP team is initiating a comprehensive functional behavioral assessment.

Given the range of possible points of entry in conducting FBAs, school psychologists are well positioned to guide educational teams in determining educational need in relation to procedural safeguards for the student and selection and use of an appropriate array of tools and procedures to gather relevant information leading to intervention (Tilly, Knoster, & Ikeda, 2000). Further, school psychologists are in an ideal position to sensitize educational teams to the impact of moving to more intensive FBA procedures in tandem with understanding the potential cost implications of more robust data collection procedures. School psychologists should guide educational teams in proceeding along this continuum in a least-to-more intrusive manner, based on student and parent preferences in relation to the success of previous interventions.

FBA and the Special Education Decision-Making Process.

Assessment and intervention for students who display behavior problems should begin at the onset of problems. FBA can be used during pre-referral intervention and in determining eligibility for, and delivery of, special education. Functional behavioral assessment is best used on an ongoing, dynamic, basis with students who display challenging behaviors, as depicted in Table 3.

Effective schools typically incorporate procedures to teach and reinforce expected behaviors and to correct inappropriate behavior. However, even in effective schools, some students will likely require a greater degree of individualization. Typically, initial interventions for this small population of students will be based on good faith and intuitive decision

Table 3. FBA throughout the special education decision-making process

Stages in the Special Education Decision Making Process	*FBA Activities*
Initial concern	• Teacher's/other's intuitive FBA as to why a particular student is exhibiting problem behavior that is based on "sensing" an increasing problem. • Intuitive decision making/intervention-prevention.
Screening/intervention	• Documentation of increasing concerns. • Failure of intuitively based interventions. • Informant methods possibly coupled with direct observation summarized in hypotheses.
Referral/full evaluation	• Continued failure of interventions based on low-tech informant methods. • More comprehensive informant methods coupled with direct observation. • Team/multiple points of input that are summarized into hypotheses.
Individual Educational Program	• Hypotheses generated from FBA serve as focal point for selection of intervention/supports. • Multi-component individualized behavior intervention plan for students whose behavior impedes their learning or that of others.
Progress monitoring and program modification	• Extend methods used during initial FBA to monitor progress. • Assess impact of intervention/supports on reductions in problem behavior, increases in acquisition and use of socially acceptable alternative skills, impact on lifestyle factors, and social validity/consumer satisfaction. • Assess environments in which to teach generalization of alternative skills and to transport necessary supports and interventions.

making. Increasingly, systematic screening and intervention procedures should be employed in instances where intuition-based interventions fail to produce desired results. Screening-level FBA and interventions usually place greater emphasis on preventative strategies in light of identified antecedents (fast triggers) and setting events (slow triggers) that adversely influence student behavior (Knoster & Llewellyn, 1998). The decision as to whether a student should be referred for a full and individual evaluation depends, at least in part, on the student's response to intervention during the screening stage.

FBA serves as a viable assessment process and is based on the requirements for full and individual evaluations in the IDEA. One provision in IDEA regarding lack of instruction is particularly important. Effective instruction for students with problem behaviors includes appropriate academic instruction and individualized behavioral intervention. In essence, the initial evaluation team must appraise the extent to which an appropriate program was in place and whether it was implemented effectively with the particular student.

The evaluation team, in conducting an FBA as part of the full and individual evaluation, provides evidence as to whether the student has a disability and needs special education. A student's response to intervention is a critical indicator of disability and the degree to which special education services are needed (Gresham, 1984, 1991). Students who make little or no progress despite support in general education, or who need extraordinary interventions, may be deemed as needing special education services and programs.

The design of an IEP for a student with problem behavior typically begins with the behavior intervention plan. Behavior intervention should be a part of the IEP if the student's behavior (a) interferes with learning (the student's or others), (b) is a result of an emotional disturbance, (c) persists despite documented interventions, (d) is a risk to safety (the student's or others), (e) results in repeated disciplinary actions that constitute a pattern, or (f) may result in a more restrictive intervention and placement (Tilly et al., 1998).

The identification and selection of well-matched strategies to address the student's needs is accomplished by the IEP team in relation to specific and global hypotheses (Bambara & Knoster, 1995, 1998). Hypotheses summarize assessment results in the form of plausible reasons for the student's problem behavior(s) and provide a foundation from which to logically link interventions addressing (a) short- and long-term prevention strategies, (b) socially acceptable alternative skills, and (c) responses to problem behaviors (including crisis management).

Monitoring student progress toward desired outcomes by IEP teams is required in IDEA. Therefore, IEP teams should employ a similar combination of informant methods and/or direct observation procedures utilized during the initial FBA to monitor progress. Thus, FBA procedures are extended into the progress-monitoring phase of IEP implementation. When extending FBA procedures to evaluate the effectiveness of a behavior intervention plan, school psychologists should guide the IEP team to consider four important questions. First, what type of information is needed to evaluate specific intervention components? Second, how will the IEP team collect this information? Third, how will the IEP team use the information to make decisions? Fourth, how will the IEP team communicate those decisions, to whom, and in what time frame? (Bambara & Knoster, 1998).

FBA Critical Components

School psychologists can significantly influence how FBAs are implemented in school programs. First, the role of the school psychologist in guiding the assessment process can directly influence how students are instructed (i.e., functional assessment). Second, school psychologists, as a result of their expertise in informant methods and direct observational procedures, can influence what information is collected and how that information is used (i.e., gathering information and forming hypotheses). Therefore, it is important for school psychologists to have a thorough understanding of the critical components of FBA, as depicted in Table 4.

It is important to understand the relationship between each critical component of the FBA process and subsequent educational team-related activities associated with intervention. To effectively guide school-based teams in conducting FBAs, school psychologists will need to have a thorough understanding of assessment and intervention practice as well as efficient strategies to engage student support team members in each step of process depicted in Table 4.

Table 4. Critical components of FBA

Step in the Problem Solving Process	*Critical Component of FBA*
Problem identification	• All relevant parties participate (i.e., those who know the student, work with the student, and/or will be affected by results of intervention). • All relevant information is considered. • Problem behaviors are operationally/environmentally defined. • Appropriate resources and precision in intervention is determined in relation to the degree of need presented.
Problem analysis	• Multi-method/multi-informant procedures are employed. • Specific and global hypotheses formulated.
Plan development	• Individualized, multi-component behavior support plan devised that 1. Focuses on measurable outcomes 2. Is based on hypotheses 3. Identifies roles and responsibilities of staff 4. Identifies progress monitoring procedures 5. Identifies necessary supports for school personnel 6. Represents a good contextual fit/social validity
Intervention and evaluation	• Progress monitoring occurs in terms of both fidelity of intervention and impact on student behavior. • Trends in student performance are analyzed. • Ineffective interventions/strategies are modified based on hypotheses. • Interventions/supports are modified to meet emerging needs. • Impact measures are taken concerning behavioral changes, impact on broad lifestyle factors (i.e., quality of life), and consumer satisfaction.

FBA and Professional Development

While the professional development implications for school psychologists relevant to FBA include a thorough understanding of methodologies for data collection, expertise is also required in understanding efficient methods of supporting educational team members in participating in each phase of intervention. Table 5 highlights professional development implications related to FBA for school psychologists.

A comprehensive training curriculum promotes the development of a range of technical skills and competencies focused on creating individualized, assessment-based, interventions that not only improve behavior but also enhance overall quality of life (Dunlap et al., 2000). As can be seen in Table 5, it is important for school psychologists to develop expertise in both the content/practice of FBA and in the process skills as they relate to educating students with problem behavior.

BEST PRACTICES IN FUNCTIONAL BEHAVIORAL ASSESSMENT

A Model for Understanding Behavior in School Settings

School psychologists are well trained to conduct assessments to determine eligibility for special education services. However, assessment for the purpose of addressing student problem behavior requires a different approach, one that is inextricably linked to the intervention process in a formative manner (Lentz & Shapiro, 1986). Functional behavioral assessment refers to a range of strategies intended to identify the variables that influence behavior in the natural environment. The purpose of FBA is to assist school-based teams in identifying the function of problem behavior and to use this information in the design and delivery of a behavior support plan (Horner, 1994; Lewis & Sugai, 1996a; O'Neill et al., 1997). In the process of conducting an FBA, specific antecedent

Table 5. FBA professional development implications for school psychologists

Skill Domain	*Competencies*
Content/practice	• Demonstrates understanding of best practice in the quantification and summarization of student behavior and environmental factors in conducting FBAs. At a minimum, these quantification procedures must include informant methods and direct observational procedures. • Gathers relevant information regarding the student, environments, and problem behavior in a time efficient manner. • Versed in collecting broad (global) and specific information by using a variety of methods. • Translates broad and specific information collected through FBAs into specific and global hypotheses. • Designs interventions with team members that are based on specific and global hypotheses. • Understands, and guides, educational teams in conducting FBA within context of progress monitoring procedures. • Graphically displays data for team interpretation. • Efficiently communicates how effective practice in FBA affects school policy and practices.
Process	• Assesses and effectively influences environmental inhibitors for educational team members as they relate to conducting FBAs and effectively intervening with students. • Collaborates with staff, families, and the student (where appropriate) to design and implement interventions that are derived from hypotheses and create a good contextual fit for the student and the student's support team. • Understands and guides implementation of FBA within context of progress monitoring procedures. • Facilitates effective communication and problem solving among team members.

and consequent events are identified and the relationship of these events to the problem behavior is defined. The FBA is considered complete when (a) the problem behavior is operationally defined, including descriptions of response classes and the sequence of behavior; (b) the antecedent events that predict the occurrence and nonoccurrence of target behaviors, including the influence of establishing operations, are identified; (c) the consequent events that maintain problem behaviors are specified; (d) the hypotheses specifying the setting events, immediate antecedents, and function of the problem behavior are developed; and (e) the direct observational data are collected to provide correlational support for the hypotheses (Bambara & Knoster, 1995; Horner, 1994; Horner, O'Neill, & Flannery, 1993; Kennedy & Itkonen, 1993; O'Neill et al., 1997).

When conducting FBAs in schools, school psychologists have the freedom to choose from a number of assessment strategies to meet the varied demands of the situation. These strategies are encompassed within three general methods, or stages, of the FBA process that vary in intensity and yet are designed to be accumulative of the information collected at each stage. The methods include (a) informant methods, (b) direct observational methods, and (c) experimental or functional analysis (Iwata, Dorsey, Slifer, Bauman, & Richman, 1994; O'Neill et al., 1997; Vittimberga, Scotti, & Weigle, 1999).

Informant Methods

Informant methods refer to indirect measures of behavior that may include the use of questionnaires, checklists, behavior rating scales, and interviews. Informant methods are just that—methods by which one individual or a group share information, in verbal or written form, about the behaviors of a student. Informant methods, although pragmatically useful in a school setting, rely on subjective impression as opposed to observation, which is considered to be more objective and, as such, have been criticized for their psychometric qualities, including inter-rater reliability and predictive validity (Shapiro, 1987). On the other hand, data collected through checklists, behavior rating scales, and interviews typically provide more behaviorally precise information than personality measures and offer opportunities for empirical validation through direct observation.

QUESTIONNAIRES, CHECKLISTS, BEHAVIOR RATING SCALES

There are a large number and wide variety of checklists and behavior rating scales that may be employed as measures of student behavior. These measures are typically used as screening instruments in that they provide useful information and a focus for later interviews. Checklists and behavior rating scales may include simple descriptions of behavior, normative- and criterion-referencing, or even broad and narrow band empirically derived factors. However, to be most useful in the functional assessment process, checklists providing the most precise behavioral descriptors are preferred.

Checklists and behavior rating scales are paper-and-pencil measures usually completed by a teacher or parent and, at times, by the individual student. These measures typically require that informants endorse discrete behaviors from a larger list and/or provide a rating (Likert-type) with regard to the level of acceptability or intensity of the behavior.

There are a number of advantages associated with the use of checklists and behavior rating scales (Merrell, 2000). First, such measures are economical with regard to completion time. Checklists and behavior rating scales usually contain explicit instructions and may be left with teachers or parents for later completion. Second, many of the checklists or behavior rating scales sample low frequency, but significant, behaviors that are not often identified through direct observation (e.g., aggressive and assaultive behaviors). Third, data from checklists and behavior rating scales are more reliable than that obtained through unstructured interviews. Finally, checklists and behavior rating scales provide a comprehensive sampling of behavior, capitalizing on the judgments and observations of those who are familiar with the student in question and have had ample opportunities to observe the student in context over a specified period.

Along with advantages, Shapiro (1987) cites a number of limitations to the use of checklists and behavior rating scales. These limitations often include biases imposed by the indirect measurement format. Most notable are (a) the information obtained may be subject to the demand characteristics, social desirability, and expectations of the respondent; (b) the data are often retrospective; and (c) the information obtained may be influenced by subjective opinion. Nevertheless, checklists and behavior rating scales are considered valuable screening measures.

Two measures of recent development depart slightly from the traditional format for checklists and rating scales: informants are used to rate a singular behavior and to summarize the data across "behavioral functions." The Motivation Assessment Scale (MAS) (Durand, 1990) is a questionnaire designed to identify occurrence patterns for specific behaviors. For each identified target behavior (e.g., hand biting) the informant responds to a series of 16 questions addressing the conditions that may or may not be associated with the behavior. Responses are then summarized according to the perceived function served by the behavior (i.e., sensory, escape, access attention, and access tangible). Durand and Crimmins (1988) report relatively high inter-rater (.80–.95) and test-retest (.89–.98) reliability coefficients for this measure. As well, a strength of the scale is that predictive validity measures were obtained by comparing teachers' ratings on the MAS with students' behaviors observed in analogue assessment conditions. In all cases, teachers' ratings predicted performance in the analogue assessment. It should be mentioned, however, that all psychometric evaluations conducted with the MAS involved students with severe mental retardation or autism who engaged in high rates of self-injurious behavior (Durand, 1990; Durand & Crimmins, 1988).

Similar to (and adapted from) the MAS, the Problem Behavior Questionnaire (PBQ) (Lewis, Scott, & Sugai, 1994) is a 15-item measure designed to assess the degree to which a specific problem behavior is influenced by teacher attention, peer attention, or the occurrence of environmental events. The PBQ is designed as a screening tool to identify initial hypotheses about behavioral function for students with mild learning and behavior problems. The tool is limited, however, in that there has only been one attempt to demonstrate its predictive validity.

INTERVIEWS

The purpose of the interview in the FBA process is to narrow the range of factors that influence problem behavior (Horner & Carr, 1997; Schill, Kratochwill, & Gardner, 1996). The interview is a valuable tool for "contextualizing" problem behavior, identifying clearly associated environmental events, and dismissing those variables not likely associated with the behavior of concern. Interviews may be structured, semi-structured, or open-ended, may involve the interviewer and interviewee, or may be completed as a self-interview process. Most importantly, the person interviewed should have direct contact with and knowledge about the student and the student's behavior.

Interviews are one of the more frequently employed techniques in behavioral assessment. There is evidence to suggest that the inter-rater reliability and criterion-related validity of behavioral interviewing is adequate, with the exception of interviews conducted with children (Gresham, 1984). The psychometric qualities of behavioral interviews improve with training and structure (Bergan, 1977; Bergan & Kratochwill, 1990; Bergan & Tombari, 1975). As with all indirect measures, behavioral interviews rely on the subjective impressions of others, which can be influenced by recent and/or salient events (Horner & Carr, 1997).

According to O'Neill et al. (1997), the four main outcomes to be achieved through behavioral interviewing include (a) a complete description of the problem behavior, (b) the identification of antecedent events (including internal processes) that may predict the occurrence and non-occurrence of the problem behavior, (c) the identification of behavioral functions based on maintaining consequences, and (d) the development of summary statements (i.e., hypotheses) to describe the relationships between the problem behavior and associated environmental events. This information can be obtained by school psychologists through the behavioral interviewing process. One sample format for conducting a behavioral interview is the Problem Identification Interview (PII), developed and evaluated by Bergan and colleagues (Bergan, 1977; Bergan & Kratochwill, 1990; Bergan & Tombari, 1975). In conducting the PII, school psychologists request information about antecedent, sequential, and subsequent events surrounding problem behavior. Following from the PII, the Problem Analysis Interview (PAI) is then conducted to validate the problem based on the collection of baseline data and to clarify the behavioral sequence of events, including those factors maintaining the behavior of concern (Schill et al., 1996). From this information, hypotheses about the function of problem behavior are formulated and an intervention plan is developed.

The Functional Assessment Interview (FAI) (O'Neill et al., 1997) is one of the more comprehensive structured behavioral interviews developed. The FAI consists of 10 separate sections, any or all of which may be incorporated into the interview. The FAI differs from Bergan's (1977) PII and PAI formats in that, in addition to clearly defining the target behavior and the events surrounding the behavior, the FAI requests information about the efficiency of the problem behavior (i.e., how readily it leads to reinforcement for the individual), possible functionally equivalent alternative behaviors, and the history of previous interventions. Upon completion, the interviewer is provided with a model to integrate information into "summary" statements or hypothesis statements.

When FBA is used to address the problem behaviors of students, the students themselves may be actively included in the process. Several researchers have examined the possibility of using students as key informants (Kern, Dunlap, Clarke, & Childs, 1994; O'Neill et al., 1997; Reed, Thomas, Sprague, & Horner, 1997). Structured, student-based interviews, including the Student-Assisted Functional Assessment Interview (Kern et al., 1994) and the Student-Directed Functional Assessment Interview (O'Neill et al., 1997; Reed et al., 1997), have been used to gather information from students. Although the psychometric integrity of student-based interviews remains questionable (Gresham, 1984), perhaps the greatest advantage lies in the possibility of discovering unforeseen maintaining consequences, alternative behaviors to be reinforced, or even potential reinforcers. Since the student-based interview process only takes an average of 20–40 minutes, the time may be well spent.

Once interview data have been collected and summarized, it is a good idea to compare information collected across informants. In qualitative research design, this process is known as "triangulation" and is used to corroborate information collected from different sources (Van Acker, 1999; Wiersma, 2000). Given the concerns regarding the reliability and validity of indirect assessment, triangulation helps to ensure the sufficiency of the data collected. When there is little convergence, or agreement, across data sources, additional and more rigorous assessment may be required.

THE INITIAL LINE OF INQUIRY (ILI)

One example of using informant methods to develop initial strategies to intervene on student problem behavior is the ILI (Knoster & Llewellyn, 1998; Lohrmann-O'Rourke, Knoster, & Llewellyn, 1999). The ILI resulted from a collaboration between the

Tri-State Consortium on Positive Behavioral Support (including the states of Pennsylvania, Virginia, and West Virginia) and the Instructional Support System of Pennsylvania, and is used as an initial screening tool for identifying and analyzing patterns of problematic student behavior. The process relies on a team-based interview, which may include several concerned individuals in addition to the child (e.g., teachers, counselors, and administrators as well as family members,, and/or representatives from community agencies). A facilitator, typically a member of the core team who is knowledgeable about the ILI process (e.g., the school psychologist), leads the team through a discussion regarding the relevant factors influencing the child's behavior, including (a) setting events or slow triggers, (b) behavioral antecedents or fast triggers, and (c) behavioral consequences (Lohrmann-O'Rourke et al., 1999). Throughout the process, emphasis is placed on user-friendly language and helping team members to reach consensus.

The facilitator uses a flipchart that is organized with columns to record information. Most times the process can be completed in one session of 60–90 minutes. Occasionally a second session is required. The process ends when the team identifies relevant factors related to the child's problem behavior and generates specific and global hypotheses about behavioral function. Team members then brainstorm a variety of support strategies, selecting those that appear to hold promise for resolving the situation while providing the best contextual fit.

The ILI, like other informant methods, is not intended to replace more comprehensive assessment strategies but, instead, should serve as a good starting point from which initial hypotheses leading to intervention may be developed. In general, when data collected primarily through informant methods is insufficient for hypothesis generation, school psychologists should move to the next stage of information gathering; that is, descriptive or direct observation.

Direct Observation Methods

Conducting a direct observation of the student in the natural setting is often necessary in order to develop and refine hypotheses about problem behavior (O'Neill et al., 1997). In particular, when data from informant methods are inconclusive, the development of hypothesis statements will be dependent upon direct observational data.

EVENT RECORDING

Methods of implementing direct observation vary along a continuum of structure and complexity. Less structured direct observations may be carried out by teachers and other classroom personnel by asking them to record each occurrence of the behavior.. Adding information about antecedent and subsequent events surrounding the target behavior enhances the data without necessarily complicating the collection process. There are myriad forms for event recording described in the literature. Figure 2 shows one example of a simple event recording form designed to capture information about the target behavior, including the time of occurrence, antecedent, and consequent information.

Another event recording tool that is easily used in a classroom setting is the scatter plot. Use of the scatter plot facilitates the identification of broader environmental events that may occasion problem behavior (e.g., lunch time) and helps to identify an individual's pattern of responding across time (Touchette, MacDonald, & Langer, 1985). Observers record when, during the day, the problem behavior occurs and, once a pattern of occurrence is defined, hypotheses about setting events and specific antecedents are developed. The scatter plot can be adapted to assess the behavior of students in both general and special education programs for a full day, or portions of the day. Figure 3 shows an adapted version of the scatter plot for use in a single classroom setting.

The Functional Assessment Observation Form (FAO) (O'Neill et al., 1997) is one of the more comprehensive tools utilized by teachers or others to organize observational data. The format allows for the recording of behavioral events as well as contextual information (e.g., antecedents and actual consequences). Like the scatter plot, the FAO may be utilized in one or in several different classrooms. It is designed to capture information on one or more behaviors and leads to a summary of the data, including predictors and perceived functions. With all information captured on a single, standard form, data can be collected across several days and summarized for further analysis.

DESCRIPTIVE ANALYSIS.

A somewhat more complex, yet highly informative, method of collecting direct observational data is through descriptive analysis. A descriptive analysis examines the natural covariation between problem behavior and antecedent/setting and consequent events (Mace, Lalli, & Lalli, 1991). Data from a descriptive analysis highlights potential functional relationships between problem behavior and environmental events, leading to hypothesis development.

Conducting a descriptive analysis in the school setting requires the services of a school psychologist who is adept at conducting structured observations. Although the task can be time consuming, there are several advantages to this form of direct observation, including (a) the opportunity to identify naturally occurring antecedents and/or reinforcers not previously identified via informant methods and (b) the possibility of creating more contextually appropriate analogue conditions should an experimental analysis be required in the future (Mace et al., 1991).

Perhaps the most common form of descriptive analysis is a method involving the continuous recording of naturally occurring antecedent, behavior, and consequent events. Known as anecdotal or A-B-C

recording, this form of descriptive analysis is designed to provide information about the target behavior, as it occurs in context, and associated antecedent and subsequent events (Bijou, Peterson, & Ault, 1968; Cooper, 1981; Cooper, Heron, & Heward, 1987). Anecdotal recording results in a narrative description of events rather than a frequency count of behaviors. Anecdotal recording requires the full attention of the observer. Generally, anecdotal recording is carried out for short time periods (20–30 minutes), several times weekly, until a clear picture of the behavior and contextual influences emerge.

Several researchers have examined the use of descriptive analysis methods yielding data in the form of conditional probabilities (Gunter, Jack, Shores, Carrell, & Flowers, 1993; Mace et al., 1991; Repp, 1999; Shores et al., 1993; Shores, Wehby, & Jack, 1999). Conditional probabilities reflect the degree or extent to which a particular target event occurs relative to another given event (Bakeman & Gottman, 1986). For example, a conditional probability establishes the likelihood that disruptive behavior (i.e., target event) follows hand raising (given event) for a particular student in a classroom setting (Gunter et al., 1993).

Mace et al. (1991) incorporate an open-ended format for descriptive analysis. Target behaviors are identified and observed, using a 10-second recording interval, while antecedent and subsequent events are identified and recorded during the observation process. Conditional probabilities, then are calculated by expressing the percentage of intervals in which a particular antecedent event (i.e., given event) is followed (within two intervals) by a particular behavior (i.e., target event) or the percentage of intervals in which a particular behavior (i.e., given event) is followed by a particular subsequent event (i.e., target event). Figure 4 shows a sample form for the collection of descriptive data using the method described by Mace et al. (1991).

Shores et al. (1999) as well as Repp (1999) differ slightly from Mace et al. (1991) by incorporating the use of pre-established codes for recording behaviors and antecedent/subsequent events. In their model of naturalistic functional assessment (NFA), Repp and colleagues first operationally define the behavior of concern, then conduct simple, non-structured observations of the student in context, noting the antecedents and consequences for each target behavior(s). Once identified, a code is developed that includes the target behavior (and appropriate alternative behavior), antecedent events (and their opposites), and consequent events, which are typically related to standard functions of behavior (escape/avoidance, attention, sensory regulation). Like Mace et al., observations conducted in the natural environment yield conditional probabilities, summarizing the percentage of intervals in which the target behavior follows specific antecedents and precedes specific consequences.

Direct observation of a student's behavior in the natural environment is an important component of the FBA process because it provides correlational support for hypotheses generated about the behavior of concern. School psychologists must be knowledgeable about, and facile with, direct observational methods. In cases where it becomes necessary to conduct an experimental analysis to determine behavioral function, a prior direct observation, or descriptive analysis, may help the school psychologist to formulate more contextually appropriate experimental conditions.

EXPERIMENTAL ANALYSIS

Experimental, or functional, analysis is a process that involves the systematic manipulation of environmental variables, under contrived or analogue conditions, to determine the variable's effect on problem behavior (O'Neill et al., 1997). The original methodology of functional analysis was pioneered by Iwata et al. (1982, 1994) in the treatment of self-injurious behavior.

Early research efforts exploring the utility of functional analysis focused exclusively on individuals with mental retardation. These early studies clearly demonstrated that problem behavior serves a function for the individual (in some cases multiple functions) maintaining and strengthening the behavior through (a) positive reinforcement, (b) negative reinforcement, and/or (c) stimulation/sensory regulation (Mace et al., 1991; Repp, 1999). Since these early efforts, numerous studies have replicated and extended the work in functional analysis to other populations and problem behaviors.

Until recently, functional analysis has been exclusively implemented in clinical settings. Given the importance of this work, there is much interest in implementing functional analysis in schools. However, constraints imposed by a non-clinical setting limit the viability of conducting an experimental analysis of student behavior. These limitations include the time, expertise, and expense of implementing analogue conditions, including the time to identify and plan the conditions, ethical concerns regarding manipulations (e.g. withdrawal of intervention), and the expense of using additional personnel as observers, confederates, and, in extreme cases (e.g., self-injury), to help in ensuring the student's safety. Moreover, for students who display more complex learning and social behavior, such as students in general education, there is also the concern that controlled manipulations of environmental events, via analogue assessment, would likely result in a high degree of subject reactivity yielding little useful information. Peer attention, for example, is one variable that often serves to reinforce student problem behavior yet is difficult to capture and assess in a contrived assessment situation (Broussard & Northup, 1995; Dunlap et al., 1993; Haring, 1992; Lewis & Sugai, 1996b; Northup et al., 1995).

However, despite these concerns, there are times when experimental analysis is necessary, including (a) when plausible hypotheses cannot be formulated based on informant or descriptive approaches and (b) when it is absolutely necessary to have a precise understanding of the nature of the problem behavior, including when, where, and, most importantly, why the behavior occurs (O'Neill et al., 1997). The latter situation is most likely to be encountered when the problem behavior is extreme (e.g. self-injury).

There are two basic approaches to conducting an experimental, or functional, analysis: (a) manipulating structural or antecedent events including instructions, directions, the presence of particular individuals, and/or the absence of all other individuals (i.e., leaving the student alone); and (b) manipulating consequent events, including contingent attention or contingent escape from the demand or task (O'Neill et al., 1997). There are also standard single-case designs that have been employed, including the withdrawal (ABAB) design and the alternating treatments design (Barlow & Hersen, 1984). In the standard model of functional analysis, observations are conducted across several sessions until a clear pattern emerges showing differences in the rate of problem behavior based on condition. However, one of the difficulties associated with this model is the number of observations required that can easily extend to more than 10 per condition depending on data variability and overlap. Recently, an alternative model of conducting functional analysis—brief functional analysis—has been developed and tested as a viable option for applied settings such as schools.

In an early study to explore the feasibility of brief functional analysis, Cooper and associates (Cooper, Wacker, Sasso, Reimers, & Donn, 1990) developed and implemented the model with eight children of normal intelligence, ranging in age from 4 to 9 years, referred to an outpatient diagnostic unit for disruptive behavior. Results showed that for seven out of the eight children, the percentage of appropriate and problem behavior varied substantially based on the assessment condition. Conditions were designed to evaluate the effects of different task demands (easy versus difficult) and parental attention (attention versus no attention). All children were assessed within a time span of 90 minutes, and treatment recommendations were rated by parents as both effective and acceptable.

Replicating and extending the work of Cooper et al. (1990), Northup et al. (1991) evaluated the aggressive behaviors of three individuals with severe disabilities who were referred to an out-clinic service for aggressive and self-injurious behavior at the University of Iowa. Results of the analogue assessment identified clear maintaining contingencies for the target behaviors. The treatment condition, then, was designed to produce that same contingency only for the occurrence of a specific alternative behavior (i.e., contingency reversal). Substantial reductions in aggressive behavior across all individuals were observed during each of the contingency reversal conditions.

The results of Cooper et al. (1990) and Northup et al. (1991) show promise for the implementation of experimental analysis in school-based settings where school psychologists and other personnel have limited time to conduct assessments. However, despite the advantage of time efficiency, conducting brief functional analyses in schools will necessitate that certain conditions be met. For example, because of the short time frame for assessment, the target behavior should occur at a steady and high frequency. Also, analogue conditions should be planned incorporating antecedent or consequent events that will have an immediate impact on the behavior of concern. Finally, school psychologists planning to conduct a brief functional analysis of behavior should be sufficiently skilled in the process to plan and readily adjust analogue conditions as necessary (Cooper et al., 1992; Derby et al., 1992; Vollmer & Northup, 1996).

Hypothesis Development and the Competing Behavior Model

The process of conducting an initial FBA culminates in the development of plausible hypotheses designed to explain the reason for the student's problem behavior. Although considered an important component of the process, hypothesis development is often overlooked by teams (O'Neill et al., 1997). Hypothesis statements are based on the results of the FBA and may emerge at any point in the FBA process. There may be several hypothesis statements developed for each problem behavior. Generally, hypothesis statements are of two types, specific and global (Bambara & Knoster, 1995, 1998).

Specific hypothesis statements are derived from interview and/or observational data. They offer an explanation of the student's problem behavior by identifying the behavioral antecedents and consequences surrounding the behavior. Specific hypothesis statements are developed for each major predictor and for each behavior or class of behaviors serving the same function (O'Neill et al., 1997). Components of a specific hypothesis include statements about (a) distal setting events (slow triggers), (b) immediate antecedents (fast triggers), (c) problem behavior, and (d) maintaining consequences (i.e., function served). Figure 5 shows an example of specific hypothesis statements developed for different predictors, behaviors, and consequences for one student.

Figure 5. Specific hypothesis statements accounting for different predictors, behaviors, and consequences for one student

HYPOTHESIS STATEMENTS FOR EACH MAJOR PREDICTOR AND/OR CONSEQUENCE

Distant Setting Event	*Immediate Antecedent (Predictor)*	→	*Problem Behavior*	→	*Maintaining Consequence*
More likely if no breakfast	When Curtis is asked to complete difficult or nonpreferred math and reading tasks		He will yell obscenities and/or throw objects		In order to escape from the tasks
No identified distant setting event	When a peer has a toy or item that Curtis wants	→	He will pinch and/or scratch the peer	→	To try to get the person to give him the toy or item
More likely if he got little attention earlier in the day	During group work or other situations in which he is receiving little attention	→	Curtis will call out a teacher's name and/or pound and slap his desk	→	To attempt to obtain attention
More likely if mother and father (during transition related to visitation) had a verbal argument in front of Curtis	Two students or two adults arguing in front of Curtis at school	→	Curtis will scream at and grab one or both people arguing	→	In order to get them to stop arguing

From *Functional Assessment and Program Development for Problem Behavior: A Practical Handbook* (2nd ed.) by R. E. O'Neill, R. H. Horner, R. W. Albin, K. Storey, J. R. Sprague, and J. Newton © 1997. Global hypothesis statements offer broad explanations for problem behavior and may be more useful for long-term planning (Bambara & Knoster, 1995, 1998). Global hypotheses serve as summary statements that describe the influence of lifestyle, medical issues, and learning history, among other factors, on the student's behavior. This information is usually obtained through the interview process (see the FAI) or through a review of records. Attention problems, communication deficits, medication side effects, and physical and/or mental illness are all conditions that may be described in global hypothesis statements. The long-term prevention of student problem behavior can be addressed by carefully considering the influence of any of these conditions on the behavior of concern. Figure 6 shows an example of a global hypothesis relevant to the same student example depicted in Figure 5.

Hypothesis statements are fundamentally important to the design of the behavior support plan. The competing behavior model, as described by O'Neill et al. (1997) makes use of specific hypothesis statements to identify the desired behavior or "replacement" skills that may serve the same function for the individual. School psychologists skilled in the use of behavioral procedures understand that plans developed for the sole purpose of reducing problem behaviors, without targeting an increase in socially acceptable alternative skills (i.e., functionally equivalent behavior, academic and social skills, and coping/tolerance skills), are not likely to be successful nor promote durable change.

SUMMARY

Functional behavioral assessment is a problem-solving framework that leads to intervention. While required under the IDEA for students with disabilities whose behavior impedes learning, FBA has broader application. School psychologists are in a unique position to guide student-centered teams in applying FBA in schools (inclusive of the special education decision-making process). In conducting FBAs, one interview or direct observational procedure will not serve all situations (no one size fits all). School psychologists should guide teams to select appropriate assessment and intervention tools and procedures in relation to the intensity, severity, and durability of student problem behavior(s).

There are three related approaches to conducting FBAs (informant methods, direct observation, experimental analysis). Various tools and procedures exist within these three approaches that can be imbedded within the continuum of assessment procedures in schools. Functional behavioral assessment can help educators and families to (a) identify the problem behavior; (b) analyze the problem; (c) develop a plan of intervention and support; and (d) intervene, evaluate, and modify the plan of intervention as warranted. School psychologists, when addressing these four components of FBA, must have skills in both the practice of gathering information and the process of constructively engaging other team members important to the process of intervention design and implementation. School psychologists, through their

Figure 6. An example of a global hypothesis

Global Hypothesis: Curtis

Curtis is 7 years old and has been identified as having a specific learning disability in reading coupled with records indicating increasingly problematic behavior. He receives most of his IEP in general education classrooms with itinerant services for reading. Curtis enjoys physical activities (particularly soccer and baseball) as well as playing video games (e.g., Nintendo). Curtis performs best in a structured classroom environment. He seems to have the most difficulty in environments with less structure (e.g., cafeteria, playground). Curtis has had difficulties in establishing relationships with his peers since his arrival at King Elementary School 7 months ago. He lives with his mother and younger brother David. Curtis does have contact with his father (who lives nearby) on weekends and occasionally during the week, based on his father's work schedule. His mother and father are in the process of a divorce. Curtis' problem behaviors generally appear related to his difficulty in gaining attention and/or resolving or escaping difficult situations, disputes, or conflicts in a socially acceptable manner.

endeavors in conducting FBAs, can have a positive influence on policy and practice in school systems by ensuring a direct link between assessment and intervention with students who present problem behavior.

ANNOTATED BIBLIOGRAPHY

Bambara, L. M., & Knoster, T. P. (1998). *Designing positive behavior support plans. Innovations* (No. 13). Washington, DC: American Association on Mental Retardation.

This resource can be used to guide student-centered school-based teams in designing and implementing effective intervention and supports. The booklet is organized chronologically and begins with conducting an FBA, proceeds through intervention design and implementation (inclusive or progress monitoring), and then concludes with a discussion of commonly asked questions.

Cooper, L. J., Wacker, D. P., Sasso, G. M., Reimers, T. M., & Donn, L. K. (1990). Using parents as therapists to evaluate appropriate behavior of their children: Application to a tertiary diagnostic clinic. *Journal of Applied Behavior Analysis, 23,* 285–296.

This article describes the process of conducting a brief functional analysis of eight children with "conduct-type" behaviors in an outpatient setting. Experimental conditions varying task demand (easy versus hard) as well as parental attention are described in detail. Graphic displays show the performance for each subject. The article concludes with a discussion of the advantages of using brief functional analysis and potentially valuable extensions of this work.

Best Practices in Social Skills Training

Frank M. Gresham
University of California-Riverside

OVERVIEW

The ability to interact successfully with peers and significant adults is one of the most important developmental accomplishments of children and youth. The degree to which children and youth are able to establish and maintain satisfactory interpersonal relationships, gain peer acceptance, make meaningful friendships, and terminate negative or pernicious interpersonal relationships defines social competence and predicts adequate long-term psychological and social adjustment (Kupersmidt, Coie, & Dodge, 1990; Parker & Asher, 1987).

The importance of social competence is particularly salient for students demonstrating significant deficits or delays in cognitive, academic, and emotional/behavioral functioning (Gresham & MacMillan, 1997). These students might be classified into one of the high-incidence disability groups specified in the Individuals With Disabilities Education Act (IDEA) and include specific learning disabilities, mental retardation, emotional disturbance, and attention deficit/hyperactivity disorder (eligible for services under Section 504 of the Rehabilitation Act of 1973).

Social competence historically has been a fundamental criterion used to define and classify students with high-incidence disabilities. This is clear in the modern classification criteria for mental retardation, which have consistently emphasized the importance of cognitive and *social competence* deficits (Gresham, MacMillan, & Siperstein, 1995). Likewise, social competence deficits have been used in the identification and classification of students as emotionally disturbed (Forness & Knitzer, 1992; Skiba & Grizzle, 1991). In fact, two of the five criteria specified in IDEA are pivotal in identifying students with emotional disturbance: (a) an inability to build or maintain satisfactory interpersonal relationships with peers and teachers and (b) inappropriate types of behavior or feelings under normal circumstances.

Social competence deficits are critical in the development of several childhood disorders characterized by an externalizing behavior pattern such as oppositional defiant disorder, conduct disorder, and attention deficit/hyperactivity disorder (ADHD) (Achenbach, 1985; Hinshaw, 1987; Kazdin, 1987). For example, students demonstrating an antisocial behavior pattern characterized by aggression, hostility, and violation of social norms are highly resistant to intervention, particularly if intervention does not take place relatively early in the child's educational career (Walker, Colvin, & Ramsey, 1995). Kazdin (1987) suggested that, after about age 8 (Grade 3), an antisocial behavior pattern should be viewed as a chronic condition (e.g., diabetes) that cannot be "cured," but rather controlled and managed with appropriate interventions and supports.

A number of professionals have noted the importance of social competence deficits with students having specific learning disabilities (Gresham, 1992; Gresham & Elliott, 1989, 1990; LaGreca & Stone, 1990). The Interagency Committee on Learning Disabilities (1987) stated that a consensus had developed that social skills deficits represent a specific learning disability. This proposal, however, has not been adopted or widely endorsed (Gresham, 1992). Nonetheless, the literature clearly shows that many students with specific learning disabilities exhibit substantial deficits in social competence, which co-occurs with their academic difficulties (Gresham, 1992).

Finally, students with ADHD exhibit significant social competence deficits and difficulties in interpersonal relationships (Landau & Moore, 1991). Pelham and Bender (1982) estimated that over half of children with ADHD experience substantial difficulties in interpersonal relationships with other children, their parents, and their teachers. Landau and Moore (1991) suggested that these children evoke an extremely negative response from their peer group that, in turn, leads to high levels of peer rejection. These students are perceived by peers and teachers as annoying, boisterous, intractable, and irritating, much of which can be attributed to their behavioral characteristics of impulsivity, inattention, and overactivity.

It is clear that school psychologists require knowledge and skills for conceptualizing, assessing, intervening, and evaluating intervention outcomes for children having social competence deficits. The purpose of this chapter is to present readers with practical information and strategies for the conceptualization of social competence assessment and reviews intervention strategies having the most empirical support. A conceptualization and discussion of generalization and maintenance of social skills concludes the chapter.

CONCEPTUALIZATION OF SOCIAL COMPETENCE

A recent comprehensive review of theories and definitions of social skills by Merrell and Gimpel (1998) indicated that there were 15 definitions that have been used in the literature. Although many definitions and conceptualizations of social competence have been discussed, the *social validity* definition represents a particularly useful way of conceptualizing social competence (Gresham, 1983; Wolf, 1978). A social validity conceptualization defines social skills as socially significant behaviors exhibited in specific situations that predict important social outcomes for children and youth. *Socially significant* behaviors are those behaviors that treatment consumers (e.g., parents, teachers, peers) consider desirable and which predict an individual's standing on socially important outcomes. *Socially important* outcomes are outcomes that treatment consumers consider important, adaptive, and functional (Wolf, 1978). In short, socially important outcomes make a difference in terms of an individual's functioning or adaptation to environmental demands and age-appropriate societal expectations. Socially important outcomes might include peer acceptance and friendships (Newcomb, Bukowski, & Pattee, 1993), teacher and parental judgments of social competence (Gresham & Elliott, 1990; Merrell, 1993), and school adjustment (Walker, Irvin, Noell, & Singer, 1992).

The social validity definition also distinguishes between the concepts of *social competence* and *social skill* (cf., McFall, 1982). In this view, social skills are specific behaviors that an individual exhibits to perform competently on a social task (e.g., starting a conversation or entering an ongoing play group). Social competence is an evaluative term based on judgments that a person has performed competently on a social task. These judgments may be based on opinions of significant others (e.g., teachers, parents, peers), comparisons to explicit criteria (e.g., number of social tasks correctly performed), and /or comparisons to a normative sample. In short, this view of social competence considers social skills to be specific behaviors that result in *judgments* about those behaviors (McFall, 1982). In sum, social skills are behaviors that must be taught, learned, and performed, whereas social competence represents judgments or evaluations of those behaviors within and across situations over time.

BASIC CONSIDERATIONS

Assessment Issues

A comprehensive discussion of social skills assessment methods is beyond the scope of the current chapter. However, several factors should be recognized in linking social skills assessment information to intervention strategies. Social skills assessment takes place in five major stages of the assessment/intervention: (a) screening/selection, (b) classification of social skills deficits, (c) target behavior selection, (d) functional assessment, and (e) evaluation of intervention outcomes. Table 1 presents 12 major goals of social skills assessment. These 12 goals of social skills assessment can also be classified within the four stages of a problem-solving model: problem identification, problem analysis, plan implementation, and treatment evaluation (Bergan & Kratochwill, 1990).

Like all behavioral assessment methods, social skills assessment methods can be broadly classified as *indirect* or *direct* (Gresham, 1998a; Gresham & Lambros, 1998). Indirect behavioral assessment methods assess behavior that is removed in time and place from its actual occurrence. Examples of these methods include functional assessment interviews, ratings by others, peer assessment methods (e.g., peer nominations and peer rating scales), and analogue role-play measures. Direct measures assess behavior at the time and place of its actual occurrence and include naturalistic observations of social behavior (e.g., classroom and playground) and self-monitoring strategies.

SOCIAL VALIDITY OF ASSESSMENTS.

Social skills assessment methods have also been classified on the basis of a social validity criterion (Gresham, 1983). *Type I* measures represent a social valued treatment goal in the sense that social systems (e.g., schools, courts, mental health agencies) and significant others (teachers, parents) tend to refer children for evaluation and intervention based on these measures. Type I measures of peer acceptance/rejection, friendship status, teacher or parent judgments, and some types of archival data (e.g., school attendance, disciplinary referrals, school suspensions, arrests).

Table 1. Goals of social skills assessment

Problem Identification	• Identify social skills strengths
	• Identify social skills acquisition deficits
	• Identify social skills performance deficits
	• Identify social skills fluency deficits
	• Identify competing problem behaviors
Problem Analysis	• Conduct functional assessment
	• Determine the social validity of specific social skills for treatment consumers
	• Select target behaviors for intervention
Plan Implementation	• Develop intervention strategies based on assessment information
Treatment Evaluation	• Select appropriate outcome measures
	• Evaluate effects of intervention
	• Assessment generalization and maintenance of effects

Type I measures are inherently socially valid. However, a major disadvantage of these measures is that they are not particularly sensitive in detecting short-term treatment effects. Sechrest, McKnight, and McKnight (1996) argued for using the method of *just noticeable differences* (JNDs) to gauge treatment outcomes. In applying the JND approach to social skills interventions, the question is, How much of a difference in social behavior is required for it to be noticed by significant others in the student's environment? For example, large and extended increases in positive social interactions with peers in both classroom and playground settings may be required before these changes are reflected in sociometric ratings of peer acceptance, friendship ratings, and /or teacher judgments of social skills.

Type II measures have demonstrated empirical relationships with Type I measures, and, as such, serve as indicators of one's standing on Type I measures. Type II measures are not socially valid in and of themselves, but they are useful because they predict important social outcomes for students. Common Type II measures are observations of social behavior in natural environments such as classrooms and playgrounds (see Hintz, this volume). These measures have been used frequently in social skills intervention research, and they are used exclusively in applied behavior analytic studies employing single case experimental designs.

Type III measures represent the least socially valid measures in assessing students' social competence, because they show little correspondence to Type I or Type II measures (Bellack, Hersen, & Turner, 1978; Bellack, Hersen, & Lamparski, 1979; Urbain & Kendall, 1980). Several types of measures qualify as Type III measures including behavioral role-play tests, social problem-solving measures, and various measures of social cognition. Gresham (1983) argued that although Type III measures have some face validity, they do not predict important social outcomes for students.

There is little evidence that performance on Type III measures is related to the following: (a) social behavior in naturalistic settings (Type II measures), (b) teacher or parent judgments of social competence

(Type I measures), or (c) peer assessment measures such as indices of acceptance, rejection, or friendship status (Type I measures). Support for this interpretation can be found in the meta-analyses by Beelman, Pfingsten, and Losel (1994) as well as by Denham and Almeida (1987), which showed social problem-solving interventions have a relatively strong impact on social problem-solving skills measured by Type III measures but had little impact on behavior ratings or social interaction skills measured in naturalistic settings.

Taxonomy of Social Skills

A great deal of empirical research has focused on developing a taxonomy or dimensional approach to classifying maladaptive or problem behaviors (see McConaughy, this volume). Achenbach and colleagues have developed a reliable and valid classification system for externalizing and internalizing behavior patterns that are reflected in teacher, parent, and student rating scales (see Achenbach,1985).

A recent synthesis by Caldarella and Merrell (1997) provided such taxonomy in a review of 21 investigations by using 19 social skills rating scales and inventories. Studies in this analysis and synthesis of factor analytic research included 22,000 students ranging from 3–18 years of age with about equal gender representation across studies. Teacher rating scales were used in about three-quarters of the studies, with parent and self-report measures being used in approximately 19% of the studies.

Candarella and Merrell's synthesis included five broad social skills domains: (a) peer relations skills, (b) self-management skills, (c) academic skills, (d) compliance skills, and (e) self-management skills. The taxonomy presented by these authors provides useful directions for selecting target social skills domains for more in-depth and specific assessment and intervention strategies. A number of these social skills domains have been used in published social skills curricula and intervention programs (Elias & Clabby, 1992; Elliott & Gresham, 1992; Goldstein, 1988; Walker, McConnell, Holmes, Todis, Walker, & Golden, 1983). Candarella and Merrell point out that such a taxonomy is useful because it (a) provides a nomenclature to refer to typical social skill patterns, (b) identifies a profile of social skill dimensions on which students may have relative strengths and weaknesses, (c) can be used to design interventions to teach social skills, (d) can be used to measure the outcomes of social skills interventions, and (e) can facilitate theory development concerning the causes, prognosis, and responsiveness of students to social skills intervention procedures.

Classification of Social Skills Deficits

An important step in considering students' social behavioral difficulties is determining the specific type of social skills deficits they may have. Gresham (1981) first distinguished between social skills *acquisition* and *performance* deficits. This distinction is important because different intervention approaches in remediating social skills deficits are required and different settings for carrying out social skills training (e.g., pullout groups versus classroom-based interventions) are indicated. A third type of deficit might be termed a *fluency* deficit in which a student knows how and wants to perform a given social skill, but renders an awkward or unpolished performance of the social skill. A fluency deficit in this sense is not unlike beginning or inexperienced readers who can accurately decode words, but render slow, dysfluent reading performances.

Social skill acquisition deficits refer either to the absence of knowledge for executing a particular social skill even under optimal conditions or a failure to discriminate which social behaviors are appropriate in specific situations. Social performance deficits represent the presence of social skills in a student's behavioral repertoire, but the failure to perform these skills at acceptable levels in given situations. Acquisition deficits can be thought of as "can't do" deficits, whereas performance deficits are "won't do" deficits. Fluency deficits stem from a lack of exposure to sufficient or competent models of social behavior, insufficient rehearsal or practice of a skill, or low rates or inconsistent delivery of reinforcement of skilled performances.

Gresham and Elliott (1990) extended the social skills classification model to include the notion of *interfering* or *competing* problem behaviors. In this scheme, two dimensions of social behavior—social skills and competing problem behaviors—are combined to classify social skills deficits. Competing behaviors can include internalizing or over-controlled behaviors (e.g., anxiety, depression, social withdrawal) or externalizing or under-controlled behavior patterns (e.g., aggression, disruption, impulsivity).

This social skills deficit classification model is pivotal in linking assessment results to interventions for social skills deficits. It is illogical to teach social skills to students already having these skills in their repertoires (i.e., with performance or fluency deficits). Similarly, intervention procedures to increase performance of a social skill (e.g., prompting, shaping, and reinforcement) are not particularly efficient in remediating acquisition deficits. Finally, students having fluency deficits do not require the skill to be re-taught, nor do they need to increase the frequency of its awkward performance. Instead, these students require more practice (opportunities to respond), rehearsal (repetitions), and/or differential reinforcement (shaping) for fluent behavioral performances. Unfortunately, almost all social skills training studies (to be described later) have not distinguished between these types of social skills deficits in delivering interventions to remediate social behavioral difficulties (Gresham, 1998a, 1998b).

BEST PRACTICES IN SOCIAL SKILLS TRAINING

Social skills training (SST) should emphasize the acquisition, performance, generalization and maintenance of prosocial behaviors and the reduction or elimination of competing problem behaviors. A large number of intervention procedures have been identified for teaching social skills to children and youth.

Types of Social Skills Training

The school is an ideal setting for teaching social skills because of its accessibility to children, their peers, teachers, and parents. Fundamentally, social skills intervention takes place in schools and home settings both informally and formally by using either *universal* or *selected* intervention procedures. *Informal* social skills intervention is based on the idea of incidental learning, which takes advantage of naturally occurring behavioral incidents or events to teach appropriate social behavior. Most social skills instruction in home, school, and community settings can be characterized as informal or incidental. Literally thousands of behavioral incidents occur in home, school, and community settings and create rich opportunities for making each of these behavioral incidents a potentially successful learning experience.

Formal social skills instruction can take place in a classroom setting in which the entire class is exposed to a social skills curriculum or in a small group setting removed from the classroom. Walker et al. (1995) refer to these teaching formats as *universal* or *selected* interventions, respectively. Universal interventions are not unlike vaccinations, school-wide discipline plans, or school rules that are designed to affect all children under the same conditions. Universal interventions are designed to prevent more serious problems from developing later in a child's life and, as such, represent primary prevention strategies. Selected interventions are typically conducted with children who have been identified as being at risk for behavior problems and are based on an individual assessment of a child's social skills deficits and competing problem behaviors. These interventions are undertaken to prevent existing behavior problems from developing into more serious behavior problems (i.e., secondary and tertiary interventions).

Objectives of SST

SST has four primary objectives: (a) promoting skill acquisition, (b) enhancing skill performance, (c) reducing or eliminating competing problem behaviors, and (d) facilitating generalization and maintenance of social skills. It should be noted that some children would likely have some combination of acquisition and performance deficits, some of which may be accompanied by competing problem behaviors and some others that are not. Thus, any given child may require some combination of acquisition, performance, and behavior reduction strategies. All children will require procedures to facilitate generalization and maintenance of social skills.

Table 2 lists specific social skills training and behavior reduction strategies for each of the four goals of SST. School psychologists must match appropriate intervention strategies with the particular deficits or competing problem behaviors the child exhibits. A common misconception is that one seeks to facilitate generalization and maintenance *after* implementing procedures for acquisition and performance of social skills. The evidence is clear that the best practice is to incorporate generalization from the beginning of any SST program (Gresham, 1998a).

Table 2. Social skills training objectives and strategies

- I. PROMOTING SKILL ACQUISITION
  - A. Modeling
  - B. Coaching
  - C. Behavioral rehearsal
- II. ENHANCING SKILL PERFORMANCE
  - A. Manipulation of antecedents
    - 1. Peer initiation strategies
    - 2. Proactive classroom management strategies
    - 3. Peer tutoring
    - 4. Incidental teaching
  - B. Manipulation of consequences
    - 1. Contingency contracting
    - 2. Group-oriented contingency systems
    - 3. School/home notes
    - 4. Verbal praise
    - 5. Activity reinforcers
    - 6. Token/point systems
- III. REMOVING COMPETING PROBLEM BEHAVIORS
  - A. Differential reinforcement
    - 1. Differential reinforcement of other behavior (DRO)
    - 2. Differential reinforcement of low rates of behavior (DRL)
    - 3. Differential reinforcement of incompatible behaviors (DRI)
  - B Over-correction
    - 1. Restitution
    - 2. Positive practice
  - C. Time-Out
    - 1. Non-exclusionary (contingent observation)
    - 2. Exclusionary
  - D. Systematic desensitization (for anxiety-based competing behaviors)
  - E. Flooding/Exposure (for anxiety-based competing behaviors)
- IV. FACILITATING GENERALIZATION
  - A. Topographical generalization
    - 1. Training diversely
    - 2. Exploiting functional contingencies
    - 3. Incorporating functional mediators
  - B. Functional generalization
    - 1. Identify strong competing stimuli in specific situations
    - 2. Identify strong competing problem behaviors in specific situations
    - 3. Identify functionally equivalent socially skilled behaviors
    - 4. Increase reliability and efficiency of social skilled behaviors (build fluency)
    - 5. Decrease reliability and efficiency of competing problem behaviors

Promoting Skill Acquisition

Procedures designed to promote skill acquisition are applicable when children do not have a particular social skill in their repertoire, when they do not know a particular step in the performance of a behavioral sequence, or when their execution of the skill is awkward or ineffective (i.e., a fluency deficit). It should be noted that a relatively small percentage of children would need social skills intervention based on acquisition deficits: Far more children have performance deficits in the area of prosocial behavior (Gresham, 1998a).

Three procedures represent pathways to remediation of deficits in social skills acquisition: modeling, coaching, and behavioral rehearsal. Social problem solving is another pathway, but it is not discussed here owing to space limitations and the fact that it incorporates the three procedures discussed in this section. More specific information on social problem solving interventions can be found in Elias and Clabby (1992).
